Implementation aspects

What is a transaction?

- Sequence of SQL commands
- Data(base) modifications are an atomic unit

**Commit** → **O.K. accept and fix changes**

**Rollback** → **Undo changes**

A transaction is a sequence of one or more processing steps. It refers to database objects such as tables, views, joins and so forth.

Here, the following properties must be fulfilled:

■ **Indivisibility**

A transaction is atomic or, in other words, it will either be completely (all of its operations) executed or not at all ("All or nothing principle"). Example: there are no employees without salary.

■ **Consistency**

The defined integrity conditions remain fulfilled. For example, each employee has a personnel number.

■ **Isolation**

The operations within the transaction are isolated from the operations of other transactions.

■ **Permanency**

Changes that transactions have made to objects must be persistent following a system crash, for example.

ACID condition= Atomic, Consistent, Isolation, Durable.

### Concurrent (parallel) transactions

- Concurrent access to the same database object

**Synchronization logic is required!**

If several transactions want to access the same objects concurrently, these accesses must be synchronized with the help of lock management.

Since the database system allows concurrent transactions to access the same database objects, locks are required to isolate individual transactions.

Locking an object means that other transactions are not able to use it in certain ways.

The more locks that are set, and the longer these stay in place, the less concurrency is possible in database operation.

All locks are released by the end of the transaction at the latest.

### Locking objects are

- Table rows (ROW)
- Tables (TAB)
- Database catalog (SYS)

### Activation

- Implicit
- Explicit

Locking management handles three types of objects:

- Records
- Tables
- Database catalog entries

### Requesting locks implicitly

You can choose the lock type by specifying an isolation level when opening the database session. The database system then requests locks implicitly during processing of an SQL statement in accordance with the specified isolation level. All changing SQL statements (such as INSERT, UPDATE, DELETE) always request an exclusive lock.

### Requesting locks explicitly

You can use the LOCK statement to explicitly assign locks to a transaction. You can specify a LOCK option in an SQL statement to lock individual rows in a table. This is possible in every isolation level. You can use the LOCK option to temporarily change the isolation level for an SQL statement.

## SHARE lock (shared, multiple access)

- Alternate transaction may access the object for reading but not for writing purpose

## EXCLUSIVE lock (exclusive access)

- Alternate transactions may access the object for reading purpose but only without a lock (dirty read)

## OPTIMISTIC lock

- A transaction (t1) might change an object if and only if no alternate transaction has changed this object after it has been read (by t1, setting the optimistic lock)

## Read locks (share locks) refer to a row or a table.

- Once a shared lock is assigned to a transaction for a particular data object, concurrent transactions can access the object but not modify it. Other transactions can set a shared lock, but not an exclusive lock for this object.

## Read locks (share locks) refer to a row or a table.

- Once an exclusive lock is assigned a transaction for a particular database object, other transactions cannot modify this object. Transactions that check for the presence of exclusive locks, or that want to set exclusive or shared locks, conflict with the existing exclusive lock of another transaction. You cannot access the locked object.

## Optimistic lock on a row level

- An update operation on a row is only actually performed if this row has not been changed in the meantime by a concurrent transaction. If the update operation was successful, an exclusive lock is set for this row. If the update operation was not successful, it should be repeated after reading the row again with or without an optimistic lock. In isolation level 0, an explicit lock must be specified for the new read operation. In this way, it can be ensured that the update is done to the current state and that no modifications made in the meantime are lost.
- It only makes sense to use an optimistic lock if one of the isolation levels 0, 1 or 10, or 15 has been assigned. An optimistic row lock must be explicitly requested by specifying a LOCK statement. A request can conflict with an exclusive lock only.

Can an alternate transaction ... ?	A transaction holds ...					
	EXCL	SHARE	EXCL	SHARE	EXCL	SHARE
	Table lock		Row lock		Catalog lock	
lock this table EXCLUSIVE	NO	NO	NO	NO	NO	YES
lock this table SHARE	NO	YES	NO	YES	NO	YES
lock any row of this table EXCLUSIVE	NO	NO			NO	YES
lock an already locked row EXCLUSIVE			NO	NO		
lock another row EXCLUSIVE			YES	YES		
lock any row of this table SHARE	NO	YES			NO	YES
lock a row SHARE			NO	YES		
lock another row SHARE			YES	YES		
change the table definition in the catalog	NO	NO	NO	NO	NO	NO
read the table definition from the catalog	YES	YES	YES	YES	NO	YES

© SAP 2009 / MaxDB 7.8 Internals – Locking/Page 7

The above table provides an overview of possible parallel read locks (share locks) and write locks (exclusive locks).

A lock collision exists in the cases which are marked with "No"; i.e., after having requested a lock within a transaction, the user must wait for the lock to be released until one of the above situations or one of the situations that are marked with "Yes" in the matrix occurs.

Additionally, the following applies:

- If no lock has been assigned to a transaction for a data object, then a shared or exclusive lock can be requested within any transaction, and the lock is immediately assigned to the transaction.
- If a shared lock has been assigned to a transaction T for a data object, and if no lock has been assigned to any concurrent transaction for this data object, then the transaction T can request an exclusive lock for this data object and the lock is immediately assigned to this transaction.
- If an exclusive lock has been assigned to a transaction for a data object, then a shared lock can, but need not be requested for this transaction.

### **Normal**

The lock is hold until the end of the transaction. It can, as the case may be, be released explicitly.

### **Consistent**

During a table scan a previously received row lock is released if in return another row of the same table gets locked.

### **Exclusive until end-of-transaction (eot excl)**

A lock has been implicitly set during a write order and for consistency reasons has to be kept until the end of transaction (COMMIT or ROLLBACK).

### **Temporary**

In addition to row locks, a table can be locked SHARE for the duration of a mass command (e.g. update).

## DB Kernel Parameters (I)

- |                          |   |
|--------------------------|---|
| ■ MaxSQLLocks            | Max. number of locks                                |
| ■ MaxUserTasks           | Max. number of concurrent users                     |
| ■ RequestTimeout         | Max. waiting time for receiving a lock (in seconds) |
| ■ DeadlockDetectionLevel | Depth level for detecting deadlock cycles           |
- In versions smaller than 7.7 the parameters had the following names:  
MAXLOCKS, MAXUSERTASKS, REQUEST\_TIMEOUT und DEADLOCK\_DETECTION

If a lock request collides with an existing lock:

- the user waits on the existing lock, OR
- an error message is returned for the existing lock.

If the user has to wait (default), he will receive an error message after the lock request has timed out.

Timeouts are updated every 30 seconds by the Timer Task.

A deadlock occurs when two or more users mutually prevent each other from proceeding. Deadlocks are recognized down to a certain depth in the database. The users involved in the deadlock receive an error message. The deadlock is resolved.

Deadlocks that were not recognized by the system are resolved by the timeouts (transactions will be rolled back).

### Transfer row locks to a table lock

- if around 20% of the lock list entries (MaxSQLLocks) are used by one single transaction on one table
- if the number of row locks per transaction exceeds RowLocksPerTransactionThreshold % of MaxSQLLocks

### Reacting to collisions during escalation

- Continue by setting further row locks if other concurrent transactions work on the same table.
- Block execution if the mass command requests more locks than available in lock

A mass command is an SQL statement that affects multiple records.

Example: Update PERSONAL set SALARY (GEHALT) = SALARY\* 1.5 where GENDER (GESCHLECHT) = "female" (weiblich)

Default value of the parameter RowLocksPerTransactionThreshold is 50. The old name was ROW\_LOCKS\_PER\_TRANSACTION.

## System tables

- sysdba.lockstatistics
- sysinfo.lockstatistics
- sysdba.transactions

## Database console

- x\_cons <DBNAME> sh[ow] act[ive]
- the status Vwait shows:  
Task is waiting to get an SQL lock

## DBACockpit

- SQL lock overview and waiting status

■ SESSION	internal session id
■ TRANSCOUNT	internal transaction id
■ PROCESS	task id of bound kernel task
■ USERNAME	name of the user
■ DATE	Start date of database session that holds the lock
■ TIME	Start time of database session that holds the lock
■ TERMID	Terminal-ID des sperrenden Benutzers
■ REQTIMEOUT	seconds to return RequestTimeout
■ LASTWRITE	seconds since last write activity
■ LOCKMODE	lock entry
■ REQMODE	lock request entry
■ APPLPROCESS	process id of the application process (Client)
■ APPLNODE	computer name (client), where the application runs on
■ SCHEMANAME	name of the table schema
■ OWNER	owner of table
■ TABLENAME	name of table
■ TABLEID	table-ID
■ ROWIDLENGTH	length of locked key
■ ROWID	locked key
■ ROWIDHEX	hexadecimal representation of locked key
■ ...	

The system table LOCKSTATISTICS describes the current lock entries and entries for lock requests.

Using the system table LOCKSTATISTICS you can determine the following database information, among other things:

- All locks that are held on a table
- All locks that the current user is holding during his database session (if this is the current user (DBA user) or database system administrator (SYSDBA user), then all locks are displayed).

Users that belong to other user classes only see the locks held by that one user.

### Views on sysdba.lockstatistics

- DOMAIN.LOCKS and DOMAIN.LOCK\_HOLDER  
show all active locks
- DOMAIN.LOCK\_REQUESTOR  
shows all lock requests
- DOMAIN.LOCK\_WAITS  
shows owners of current lock related to current lock requests

### `SYSINFO.LOCKSTATISTICS`

- maximum number of lock entries as defined for locklist
- number of currently used entries
- average number of used entries
- maximum number of used entries
- threshold value for lock escalation
- number of lock escalations since last restart
- number of detected deadlocks since last restart
- number of transactions that hold locks
- number of transactions that are requesting locks

# Transaction DBACockpit (DB50 ) Exclusive SQL wait situations

Task-ID	Appl.-ID	Appl.-Server	Sperrt	Sperrart	Tabellen...	Task-ID	Appl.-ID	Appl.-Server	Wartet	Sperranforderung	War
46	110	10.31.165...	tab_s...	D010L		33	7058	uw1019		row_exclusive	497

© SAP 2009 / MaxDB 7.8 Internals – Locking/Page 15

Display of the current wait situations

Task 33 waits for a lock, which can then be assigned only once task 46 has provided the shared table lock.

Exclusive locks prevent other users from accessing the locked entry. These locks can significantly interfere with the performance of the SAP system and the database system.

## Procedure to determine the user who triggered the lock

- The column "Appl.ID" displays the process ID of the work process on the application server "Appl.Server". You will find the corresponding SAP work process in transaction SM51/SM50 or SM66.
- The corresponding task (here, task 46) can be aborted in the task manager under "Kernel Threads".

# General Overview DBACockpit (DB50 )

## Overview SQL Locks

46	110	10.31.165.40	tab_share				D010L	

© SAP 2009 / MaxDB 7.8 Internals – Locking/Page 16

Display of all active and requested database locks.

Exclusive locks prevent other users from accessing the locked entry. These locks can significantly interfere with the performance of the SAP system and the database system.

The system displays detailed information about the locks currently set. This display can be very long in a running SAP system. Therefore, always display the analysis of SQL locks from the overview of wait situations (exclusive).

Task T33 requests a write lock on a record belonging to the table D010L.

Task T46 holds a table lock on table D010L.

### Phenomena

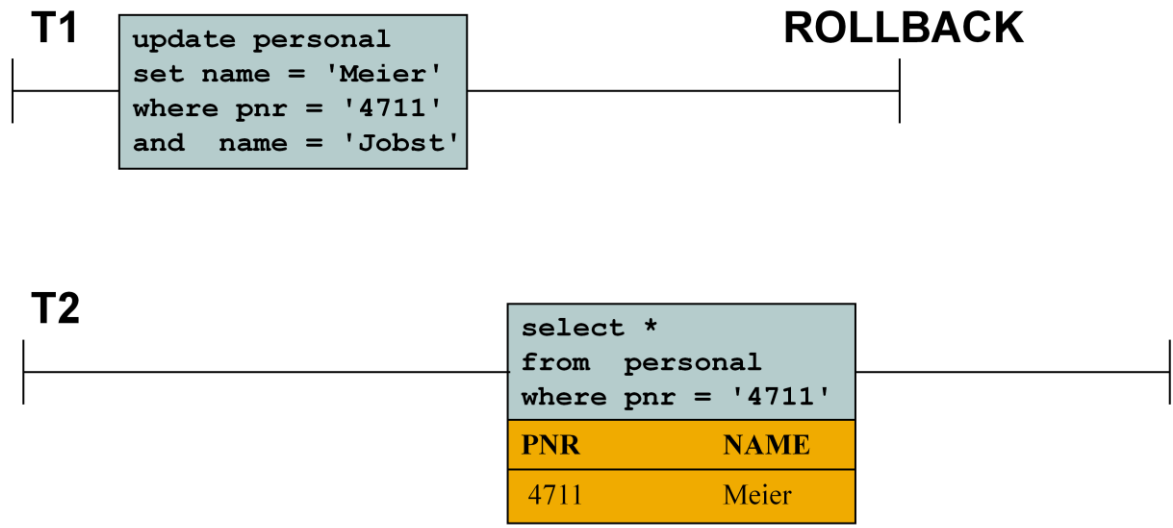

- Dirty Read
- Non Repeatable Read
- Phantom

The isolation level plays an important role in the lock activities of the database system. You use the isolation level to specify whether locks are requested or released implicitly, and how.

Your choice of isolation level affects the degree of parallelism of concurrent transactions and the consistency of the data: the lower the value of the isolation level, the higher the degree of parallelism, and the lower the degree of guaranteed consistency

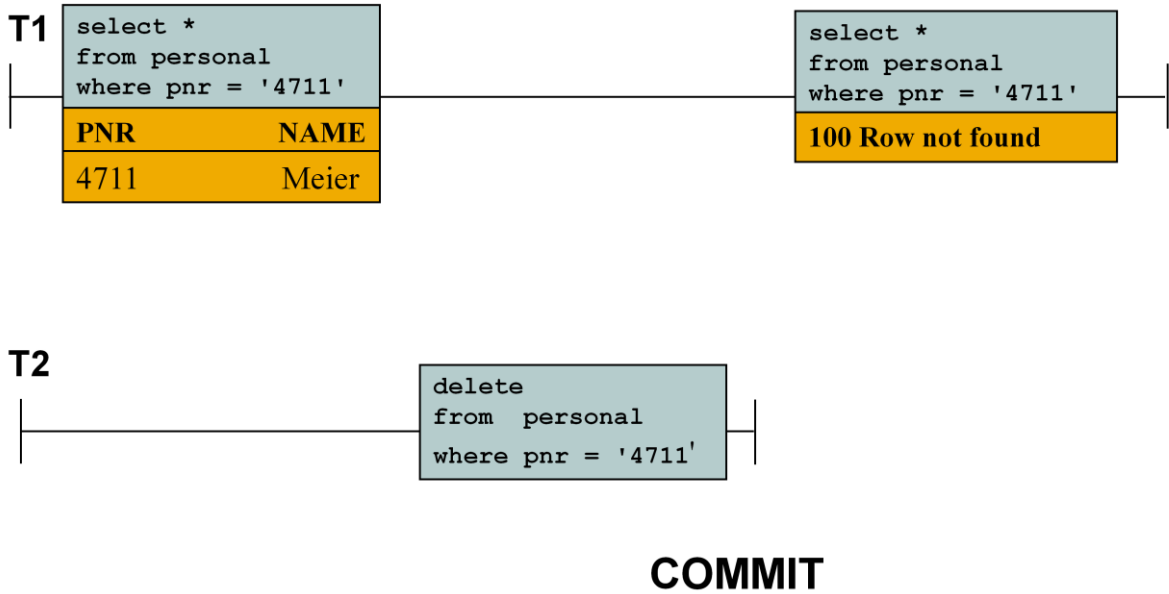

If transactions are competing for access to the same data, then different isolation levels can cause different sorts of inconsistencies. You can find a compromise between parallelism and consistency, while taking into account the requirements of your database application.

When concurrent transactions are processed, inconsistent situations can occur. Try and avoid these situations by configuring the lock behavior and isolation level of the database system accordingly.

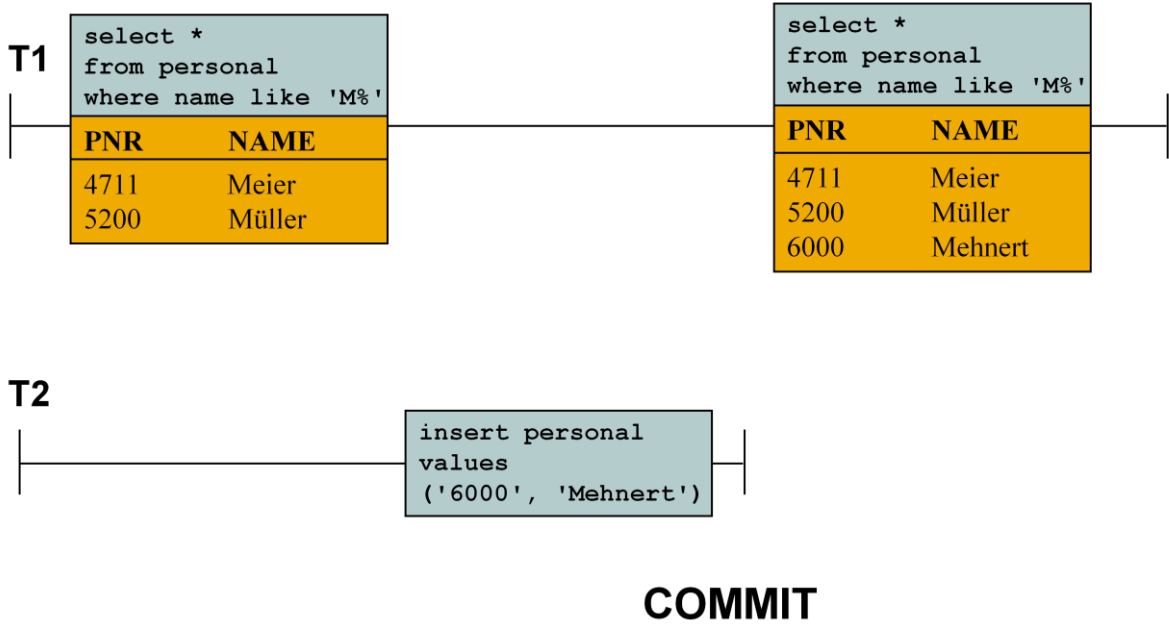

A row is modified in the course of a transaction T1, and a transaction T2 reads this row before T1 has been concluded with the COMMIT statement. T1 then executes the ROLLBACK statements. In this case, T2 read a row that never actually existed.

# Non Repeatable Read

Transaction T1 reads a row. Transaction T2 then modifies or deletes this row, and completes the action with the commit statement. If T1 then reads the row again, it either gets the modified row or a message indicating that the row no longer exists.

Transaction T1 executes an SQL statement S that reads a set of rows (M) fulfilling a search condition. Transaction T2 then inserts or modifies data, and produces another row that fulfills this search condition. If T1 then executes the statement S again, the set of rows that is read differs from the set M.

### Read access

- Rows are read without checking for lock collisions
- It is not guaranteed that
  - a repeated read within the same transaction returns the same result
  - rows once read ever will be committed (become persistent)

Isolation level 0 does not offer any protection against access anomalies.

If you specify the isolation level 0 (uncommitted), then rows are read without shared locks being requested implicitly. If a row is then read twice within a transaction, this isolation level does not guarantee that the row has the same state the second time as the first, since it could have been changed by a competing transaction between the two reads.

Furthermore, there is no guarantee that the state of a row that was read has already been recorded in the database using a COMMIT WORK statement.

T1

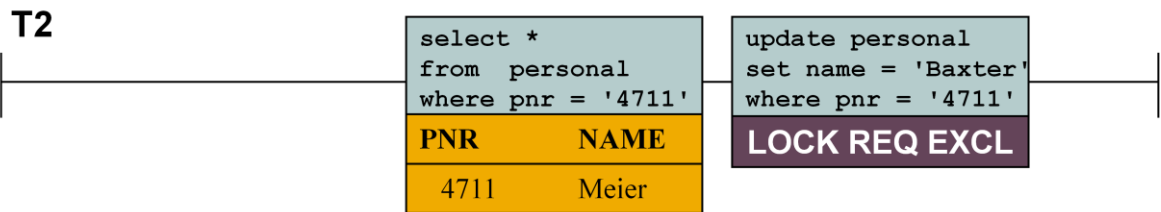

```
update personal
set name = 'Meier'
where pnr = '4711'
and name = 'Jobst'
```

ROLLBACK

T2

```
select *
from personal
where pnr = '4711'
```

PNR	NAME
4711	Meier

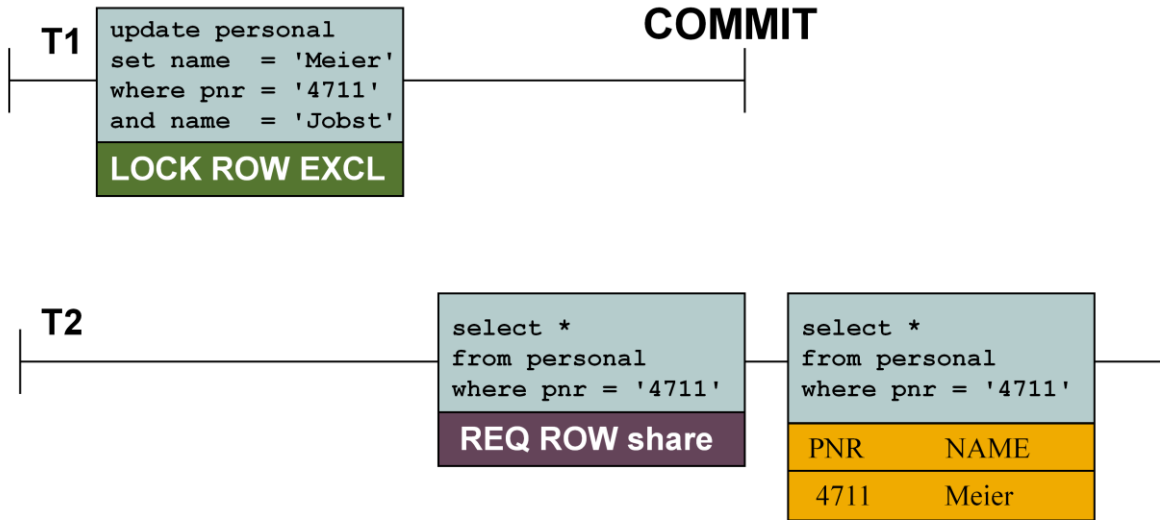

### Read Access

- Read persistent (committed) rows. Check for collision happens before reading
- In case of a collision a lock request is set. (req row share)

When you retrieve data using an SQL statement, the database system ensures that, at the time each row is read, no exclusive lock has been assigned to other transactions for the given row. However, it is impossible to predict whether an SQL statement causes a shared lock for a row of the specified table and for which row this may occur. In SAP DB versions < 7.4, the share locks were held until the end of the transaction. In version 7.4 and above, the share lock is removed after the record has been read.

Locking of data entities and optimal multi-user operation are in direct conflict with one another. It is not recognizable whether the waiting user is waiting for a lock or whether the system is running poorly.

**T1**

```
update personal
set name = 'Lutz'
where pnr = '8500'
and name = 'Bär'
```

**REQ ROW EXCL**

```
update personal
set name = 'Lutz'
where pnr = '8500'
and name = 'Bär'
```

**LOCK ROW EXCL**

**T2**

```
open cursor
select *
from personal
where pnr = '4711'
```

**LOCK tab share**

```
fetch cursor pos (1)
fetch cursor pos (2)
fetch cursor pos (1)
close cursor
```

**T2**

```
Open cursor  
select *  
from personal  
where pnr = '4711'  
for reuse
```

**LOCK tab share**

```
fetch cursor  
close cursor
```

PNR	NAME
4711	Meier

### Write access

- Goal:
  - modify tables that are committed for the duration of an SQL command
  
- Implementation:
  - temporary table locks during execution of the SQL command (tab share)
  - exclusive row locks (row excl) on new/updated rows until end of transaction

When inserting, changing or deleting rows, the exclusive locks are assigned implicitly to the transaction for the relevant rows that are not released until the end of the transaction.

### Read access

- Goal:
  - read from tables that are committed for the duration of an SQL command
  - avoid concurrent follow up modifications to the rows read
  
- Implementation:
  - temporary table locks during execution of the SQL command (tab share)
  - the rows read are secured from concurrent modifications by using share locks (repeatable read)

Isolation Level 2 safeguards against the "Non Repeatable Read" phenomenon,.

A record that is read multiple times within a transaction always contains the same values.

### Read access

- the temporary table lock (tab share) will be released
  - after execution of the SQL command, if a temporary result table is created (result is copied)
  - after closing of the result table (close)
  - at the end of the transaction
  
- the row locks will be released (row share)
  - at the end of the transaction
  - explicitly with an UNLOCK command

If you specify the isolation level 2 or 20 (repeatable), then shared locks are requested implicitly for all the tables addressed by an SQL statement data query before processing starts.

If an SQL statement generates a result table, which is not physically saved, then these locks are not released until the end of the transaction or when the result table is closed. Otherwise, the locks are released immediately after the SQL statement is processed.

The table shared lock is not assigned to the transaction with SQL statements, where exactly one row in a table is processed that is determined by key specifications or using `CURRENT OF <result_table_name>`.

In addition, an implicit shared lock is assigned to the transaction for each row read while an SQL statement is being processed. These locks can only be released using an UNLOCK statement or by ending the transaction.

# ISOLATION LEVEL 2

**T1**

```
update personal
set name = 'Busse'
where pnr = '4711'
and name = 'Meier'
```

**REQ ROW EXCL**

```
update personal
set name = 'Busse'
where pnr = '4711'
and name = 'Meier'
```

**LOCK ROW EXCL**

**T2**

```
select pnr,name
into :pnr, :name
from personal
where pnr = '4711'
```

**LOCK ROW share**

PNR	NAME
4711	Meier

```
select pnr,name
into :pnr, :name
from personal
where pnr = '4711'
```

**LOCK ROW share**

PNR	NAME
4711	Meier

**COMMIT**

### Write Access

- Goal:
  - modify tables that are committed for the duration of an SQL command
  
- Implementation:
  - temporary table locks during execution of the SQL command (tab share)
  - exclusive row locks (row excl) on new/updated rows until end of transaction

When inserting, changing or deleting rows, the exclusive locks are assigned implicitly to the transaction for the relevant rows that are not released until the end of the transaction. No locks are set for the whole table, however.

### Read access

- Goal:
  - read from tables that are committed for the duration of an SQL command
  - avoid concurrent follow up modifications to the rows read during current transaction (phantom)
  
- Implementation:
  - table locks (tab share)
  - release of share locks
    - at the end of the transaction
    - explicitly with an UNLOCK command

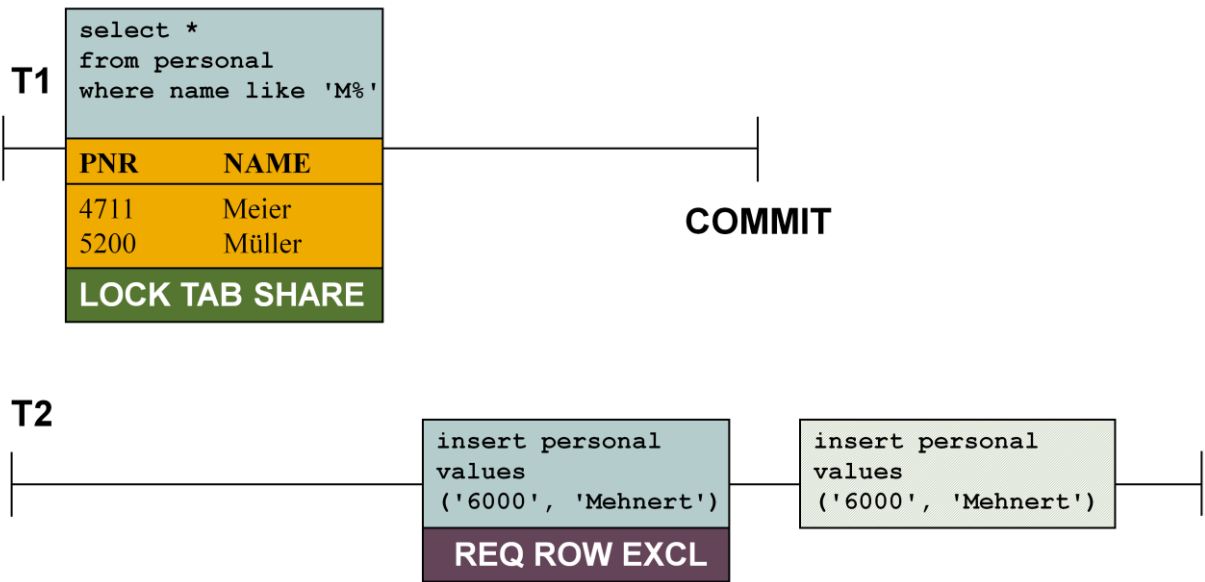

If you specify the isolation level 3 or 30 (serializable), then a table shared lock is implicitly assigned to the transaction for every table addressed by an SQL statement.

These shared locks can only be released by ending the transaction. This table shared lock is not assigned to the transaction with SQL statements, where exactly one row in a table is processed that is determined by key specifications or using `CURRENT OF <result_table_name>`.

Isolation level 3 safeguards against three types of access anomalies:

- Dirty Read
- Non Repeatable Read
- Phantom

# ISOLATION LEVEL 3

**T1**

```
update personal
set name = 'Meier'
where pnr = '4711'
and name = 'Jobst'
```

**LOCK ROW EXCL**

**ROLLBACK**

**T2**

```
select *
from personal
where pnr = '5200'
```

**REQ TAB share**

```
select *
from personal
where pnr = '5200'
```

PNR	NAME
5200	Müller

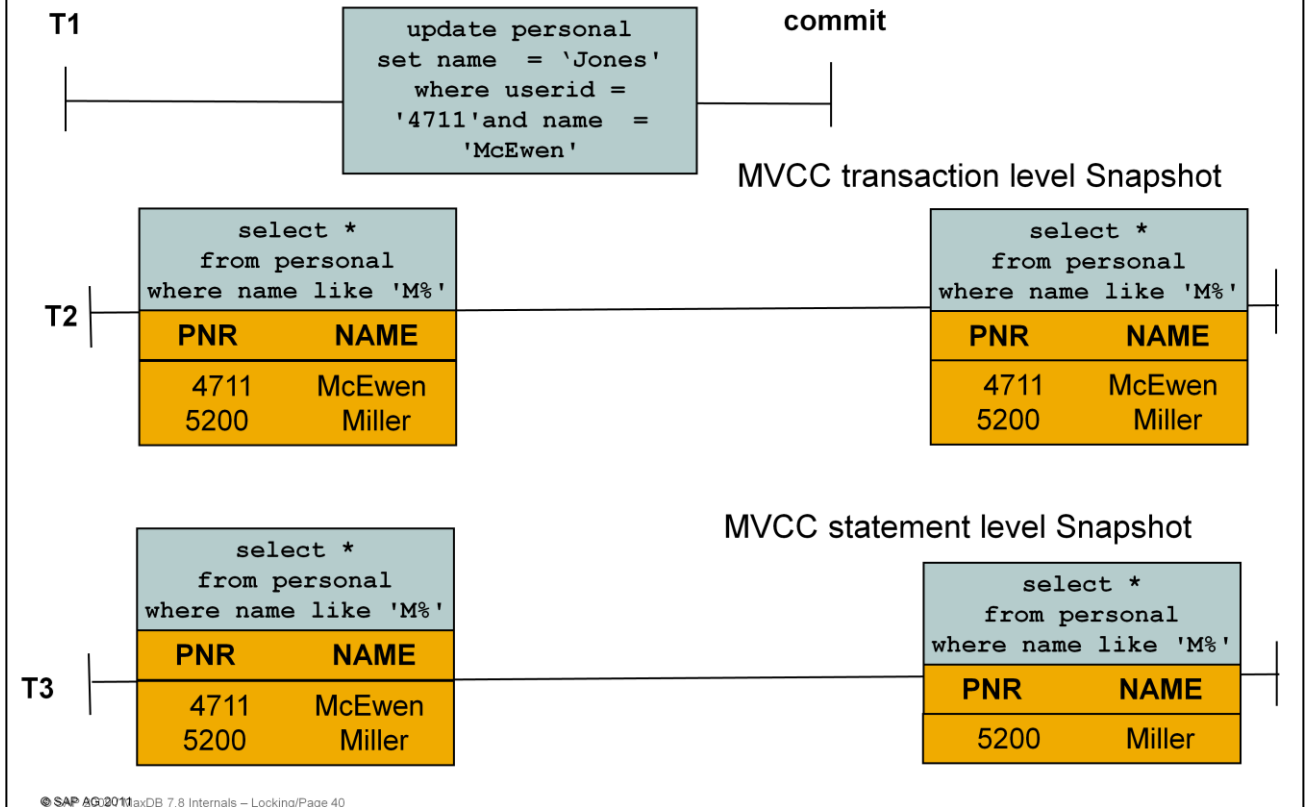

### Write Access

- Goal:
  - modify tables that are committed for the duration of an SQL command
- Implementation:
  - table locks during execution of the SQL command (tab share)
  - exclusive row locks (row excl) on new/updated rows until end of transaction

When inserting, changing or deleting rows, the exclusive locks are assigned implicitly to the transaction for the relevant rows that are not released until the end of the transaction.

# MVCC: Multi Version Concurrency Control

Multi version concurrency control ensures consistent read operations.

Concept of MVCC:

**updates do not overwrite existing records**

**updates insert new versions**

=> transactions may write a new version of some data while concurrent transactions still have **read** access to previous versions.

**Transaction level snapshot:** all statements of a transaction see the same snapshot => isolation level repeatable read

**Statement level snapshot:** different statements in a transaction may see different snapshots => isolation level read committed (non repeatable read) Each statement sees the changes that were committed when the execution of the statement started.

MVCC is not supported in MaxDB Version 7.8. You must not activate MVCC in MaxDB version 7.8

## Implementation

- Locking a row (l)
  - a row is locked by blocking the access via primary key
  - if a unique index exists, this secondary key is locked too (secure the one-to-one relation)

## Lock Key Composition

Lock keys have a maximum length of 64 Byte

A lock key consists of 4 parts:

- Start of the primary key (28 Byte)
- Tail of the primary key (28 Byte)
- Generic hash values (2 x 4 Byte)

© SAP 2009 / MaxDB 7.8 Internals – Locking/Page 42

The unique identifier of a record is the primary key. Locks using long primary key values with variable lengths would be inefficient.

Thus, for each primary key a lock key is generated if the primary key is longer than 64 bytes.

As of version 7.4, the lock key has a maximum length of 64 bytes, which is independent of the 64-bit or 32-bit architecture.

The first 56 bytes of the lock key are created from the combination of the first 28 bytes and last 28 bytes of the primary key.

The last 8 bytes of the lock key are generated using two different hash algorithms and with the help of the entire primary key. The result of the first hash algorithm is stored in the second-to-last 4 bytes and the result of the second hash algorithm in the last 4 bytes. Thus, optimum dispersion of the of the lock key values is ensured.

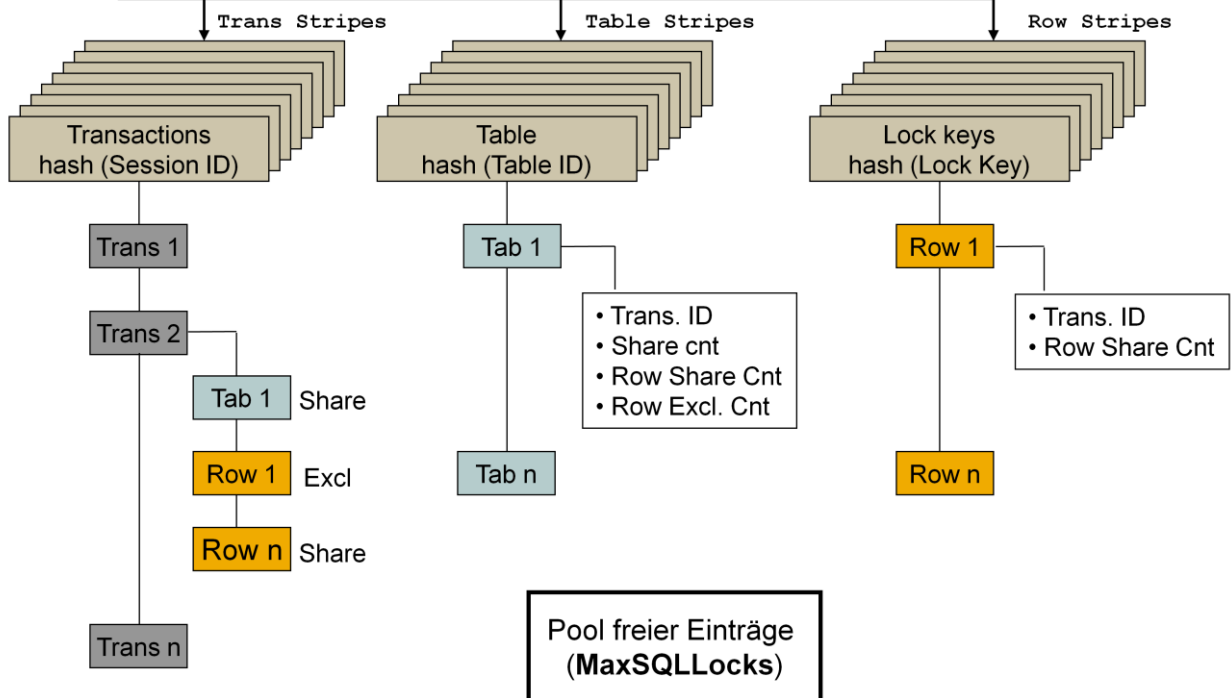

## Implementation

- Locking a row (II)
  - Accesses to LOB (former LONG) values always are secured by locks as reading and writing LOB values can require multiple I/O requests. Thus locking LOBs is independent of the ISOLATION LEVEL)
  - Locks for LOB values are realized as table locks (tab).
  - Each LOB value is identified by a unique TAB-ID, which is used to build the lock entry (i.e. the lock key)
- Read access
  - The database releases the lock immediately after the read access.

## Concept (I)

- Structure:
  - segmental list of transactions
  - segmental list of tables
  - segmental list of lock keys
  
- Views into the locklist
  - local view on transactions
  - global segment oriented view on tables
  - global segment oriented view on lock keys

UPDATE tab SET name = 'Meier' WHERE pid = 4711

© SAP 2009 / MaxDB 7.8 Internals – Locking/Page 45

## Procedure for generating a lock entry:

- Check whether the private transaction view already contains the lock entry (unprotected sequential search).
- If the lock entry is not contained in the private transaction view, the segment assigned to the table of the global table view is checked with respect to a lock collision (hash access).
- In the case of table locks, set the lock or make a lock request
- If the lock entry is not contained in the private transaction view, the segment that is assigned to the table of the global table view is checked with respect to a lock collision (hash access).
- Set the lock or make a lock request for row locks.

The transaction ID displays the exclusive lock in the table and lock key view.

In the table view, Row Share and Exclusive Counter are used to calculate the escalation.

The number of segments of each view is set using the parameters

TransactionLockManagementStripes (`_TRANS_RGNS`), TableLockManagementStripes (`_TAB_RGNS`) und RowLockManagementStripes (`_ROW_RGNS`). There are 8 segments, by default.

**End**

THE BEST-RUN BUSINESSES RUN SAP™
