When an error occurs, the first step is to categorize it, as different types of errors call for different corrective measures. In some of the cases described here, categorization is simple. In some cases, however, it may not be immediately clear which of the active components is responsible for the undesirable system behavior. It may not even be clear whether the problem has to do with the database, and thus whether the diagnosis options described in this chapter will be helpful.

Problems arising from the installation of the software are easy to identify as such.

In an SAP environment, connection problems generally manifest themselves in that the database is, in principle, ready for operation, but the client processes cannot get a connection.

If the database, without any conscious action having been taken, is no longer ready for operation, it may have crashed. However, it is also possible that the database has consciously performed an emergency shutdown due to an existing error situation.

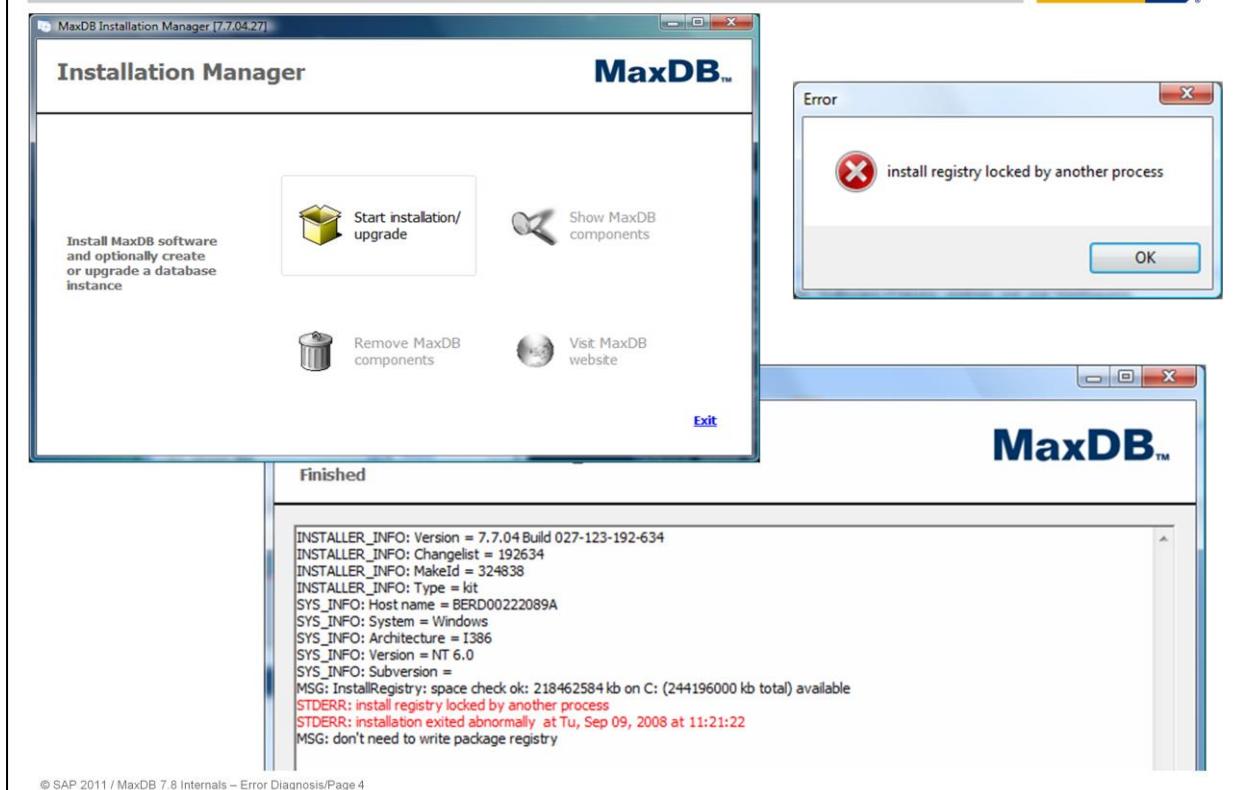

In the SAP environment, a hang situation is indicated by the presence of an hourglass. Determining the area in which a problem exists (lock collision, "blockage" of the system resources, etc.) is not necessarily insignificant.

System errors are serious errors and in the SAP system are often logged as error -602. The unique error number can be found in the ***KnIMsg (knldiag)*** file.

As a rule, transactions terminate with a short dump if an SQL error occurs.

Backup or restore problems are recognizable as such; however, problems in this area frequently are due not to the database itself, but rather have an external cause (operating system, external backup tool).

## Installation - sdbsetup

As of version 7.6 the software installation for MaxDB is done with the installation manager (**sdbsetup**). It is available for use after unpacking the software package provided on the Service Marketplace.

Both initial installations and software updates can be done by choosing “Start Installation/Upgrade”.

Deinstallations of MaxDB software can be done via “Remove MaxDB components”. Do not delete the MaxDB software with operating system resources under any circumstances!

“Show MaxDB components” provides information about installation directories, versions of the installed software elements, databases and additionally guides you to the installation log files.

Installation logs are stored in the directory <globaldatapath>/wrk ; these can be useful, even at a later point in time. The name contains the type of installation as well as a time stamp, which makes it possible to determine the corresponding package.

The <globaldatapath> can be determined by using the following dbmcli command:

- dbmcli -d <SID> -u <dbm-user>,<password> dbm\_getpath globaldatapath

More extensive migration work may be necessary if you are making a big release-jump; the procedure is described in the corresponding notes.

In the example shown above at the beginning of the installation an error occurred. The installation manager guides the user to the log file where he finds a more exact and often self-explaining error message. The installation failed as another **sdbupd** was started at the same time.

Call: **sdbinst/sdbupd**

Option **-help** lists valuable options.

Installation logs are written in <indepdatapath>/wrk.

```
MaxDBCPrecompiler_install-13.09.2004-11.34.log  
MaxDBRuntimeForSAPAS_install-26.07.2004-14.47.log  
MaxDBServer_install-02.03.2004-18.42.log  
MaxDBServer_install-29.07.2004-14.32.log  
MaxDBUninstall_install-02.12.2004-15.23.log  
MaxDBUpdate_install-01.09.2004-09.13.log
```

Deinstallation of MaxDB software: **sdbuninst** or **SDBSETUP**

No deletion with operating system!

As of version 7.6, the tool **SDBSETUP** with GUI interface is available for all supported platforms

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 5

Installation of the MaxDB software in versions 7.5 and smaller is done with the tools **sdbinst** and **sdbupd**. In the higher versions they are also part of the delivered software and can be used if the installation is not done interactively. For an initial installation, **sdbinst** is used; overwriting an older version with a current one is done with **sdbupd**.

You get the call options by entering the option **-help**.

If you encounter problems during installation, a corresponding message is issued. The message should inform you as to what error has occurred and how to fix it.

Installation logs are stored in the directory <globaldatapath>/wrk.

(Up to version 7.7 the installation logs can be found in the directory <indepdatapath>/wrk as the so-called isolated installation had not been introduced in those versions.)

**sdbinst/sdbupd** enable you to install individual components from the overall package. You use the **--package** option to specify the component(s).

You use **sdbuninst** or **SDBSETUP** to deinstall the software.

## Errors during the Installation

Examples (look for STDERR):

```
STDOUT: start extraction test run of "SAPDBBAS.TGZ"
STDERR: test run failed: cannot extract bin/dbmrpc: cannot write to /sapdb/programs/bin/dbmrpc: Text file busy - no file(s) of "SAPDBBAS.TGZ" extracted!
STDERR: maybe any sap db software is running... please stop all
STDERR: installation exited abnormally at Th, Aug 14, 2003 at 14:46:41
```

```
STDOUT: start extraction test run of "SAPDBUTL.TGZ"
STDERR: maybe any sap db software is running... please stop all
STDERR: installation exited abnormally at Th, Aug 14, 2003 at 14:48:30
...
```

```
WRN: try to install release "7.3.00.32" over existing "7.3.0.36"
MSG: update test: installed release newer
MSG: update from "7.3.0.36" to "7.3.00.32" not allowed
STDERR: cannot downgrade package
STDOUT: skipping package
```

The option `--force_extract` also substitutes files being in use.

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 6

To quickly find errors in the installation logs, look for the key word STDERR.

A common cause of errors in Windows systems is that DLLs cannot be overwritten or - more generally - that a component to be overwritten is still running (for example the x\_server).

In the first two cases you get the message that the database software has not been completely stopped, so a re-installation would fail. To identify such problems ahead of time and avoid having the installation fail half-way through, the actual installation is preceded by a test run.

As of version 7.6.01 the option `--force_extract` cares for the substitution of programs and libraries being in use by copying the existing files.

In the third example, the attempt was made to install an older version over a newer one. This is not permitted since downward compatibility cannot be ensured, for instance when loading the system tables.

## sdbverify

```
PCR 7250 7.2.05.24 in /sapdb/programs

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 7

**sdbverify** is a tool that checks all installations on a computer for completeness. During the check, any inconsistencies due to impermissible software combinations are detected.

Using the registry entries, *sdbverify* checks whether the status in the file system still corresponds to the contents of the installation package.

In the example above, it is noted that the access rights (under Unix) were subsequently changed.

The result is a summary of the installations that have been checked.

As of version 7.8.02 an option `repair_permissions` has been introduced. Inconsistencies concerning user rights can automatically be repaired.

Start **sdbverify** with user root under Linux/UNIX.

To get an overview of the registered installations, you can also use the tool **sdbregview**. If you call it with the option `-l`, it outputs a short list; without the option it outputs comprehensive information about every installation.

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 8

The tool **xinstinfo** provides a quick overview of the installation paths used on a system. It displays the "Independent Data Path" and the "Independent Program Path", or in other words, the paths that are valid for all the databases installed on the computer. The programs found there are always operated in the highest installed version (for example the x\_server).

If **xinstinfo** is called with a database name, you also get database-specific information.

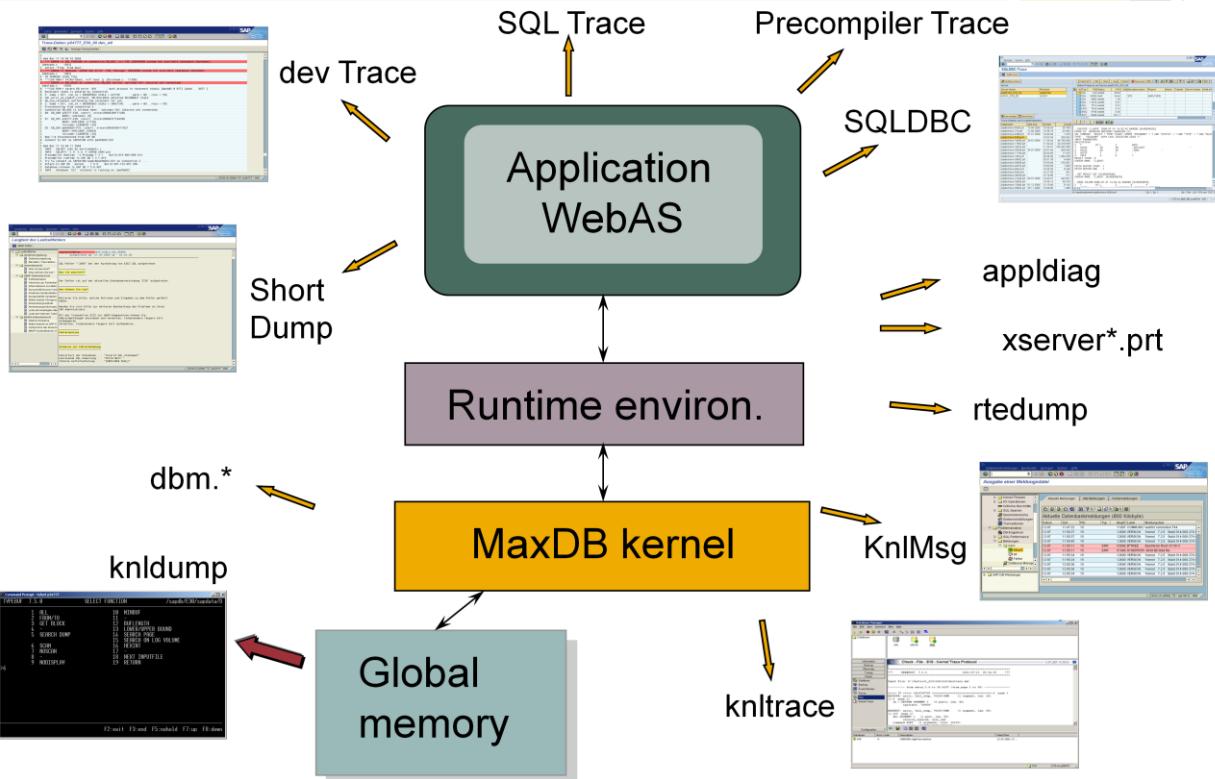

Using **dbmcli** with the entry **inst\_enum**, you get a list of the versions installed on the computer (dependent paths). The command **db\_enum** lists the databases in their different variants (fast, quick, slow, test) as well as their current operational states.

## Overview (Diagnostic and Trace Files)

- System log (SM21)
- ABAP Short Dump (ST22)
- dev logs
- SQL Trace (ST05)
- Precompiler Trace
- SQLDBC
- appldiag
- xserver\_<hostname>.prt
- dbm.prt, dbm.utl, dbm.knl, dbm.ebp, dbm.ebl
- KnlMsg (knldiag)
- Event Viewer
- knltrace
- knldump
- rtedump

# Diagnostic Files

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 10

## Short Dump

ABAP short dumps are generated by the WebAS or R/3 system when unexpected return codes occur in the SQL environment.

## dev-Trace

The Developer Traces are logs of the disp+work processes of the SAP system.

## SQL Trace

SQL commands and their runtimes are logged.

## Precompiler Trace

SQL trace of the order interface.

## SQLDBC

Trace for the SQLDBC (SQL Database Connectivity) interface.

## appldiag

If errors between the runtime environment and the kernel occur, they are entered in the *appldiag* file. This file is created for each operating system user.

## xserver\_<hostname>.prt

If errors occur during communications via the x\_server, they are entered in the *xserver\_<hostname>.prt* file.

## rtdump

If a crash occurs, the runtime environment writes its status in the *rtdump* file. It is an ASCII output of the command `x_cons <SERVERDB> show all`

## dbm.\*

Various log files for the backup environment or for logging DBM server commands.

## KnIMsg (knldiag)

The kernel writes information and messages to the *KnIMsg* file. It has a fixed size and is overwritten cyclically. After a crash, it also contains the backtrace.

## knltrace

This file is written by the kernel when the Vtrace is activated and following a crash. It has a predefined, fixed length.

## knldump

During an emergency shutdown, the global memory is written to the *knldump* file. The corresponding file system should be sufficiently large.

Transaction sm21 displays the system log of the SAP system. The system log is not written under the control of the database, but it does contain information about database errors.

# ABAP – Short Dump

The screenshot shows the SAP ABAP Short Dump interface. The title bar reads "Runtime Error Long Text". The left sidebar contains a tree view with nodes like "Runtime Error", "System environment", "Userview", "ABAP developer view" (which is expanded to show "Short text", "How to correct the error", "Information on where", etc.), and "BASIS developer view". The main area displays runtime error details: "Runtime Errors" (DBIF\_DSQL2\_SQL\_ERROR), "Exception" (CX\_SY\_NATIVE\_SQL\_ERROR), and "Date and Time" (14.08.2008 17:41:23). It also includes sections for "What happened?", "What can you do?", and "How to correct the error". The "How to correct the error" section provides a detailed SQL trace and keywords for SAP Notes search.

In the SAP system, SQL errors in the database result in ABAP short dumps when unexpected return codes occur.

They are not written under the control of the database, but they can be useful for analyzing error situations because they present a full picture of the error. SQL errors are otherwise not logged by the database, unless the Vtrace has been explicitly activated.

You can get a list of the short dumps that have occurred with transaction st22.

The short dump itself records which program and which ABAP command within it caused the error. You can then search for the error code in the notes.

If an unknown error occurs, it is often desirable to identify the command in "native SQL." To do this, in a reproducible case the SQL trace must then be activated with st05. At the same time, an analysis with the Vtrace may also be useful.

If necessary, you can find helpful information about the versions you are using in the section "How to correct the error".

## Dev Logs (1)

The screenshot shows the SAP Trace Data interface. The title bar reads "Trace Data: Id1032\_A1S\_02 dev\_w0". The main area displays developer logs (trace data) for transaction Id1032\_A1S\_02. The logs include information about the database environment, such as DBSDBSLIB version, SQLDBC client runtime, and connection details. A command history section shows the execution of various commands like "INFO : Connect to DB as 'SAPAIS'", "INFO : Database 'AIS' instance is running on '1d1032'", and "INFO : SAP RELEASE (DB) = 710". The bottom of the window shows the SAP logo and navigation links for "A1S (1) 001", "Id1032", and "INS".

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 13

The developer traces are not written directly by the database, but rather log actions of the disp+work processes of the SAP system.

The dev logs are stored in the work directory of the SAP system and have the designation **dev\_w\***. You can access them directly with transaction st11.

They are active by default; only higher trace levels have to be activated explicitly. This is generally done by the developers themselves.

However, they were included in this unit because other information relevant for the database is also stored there.

If connection problems between the disp+work processes and the DB occur, developer traces are often helpful.

Errors have a red background and thus are easy to find.

Among other things, it is easy to find the version of SQLDBC or the precompiler environment being used.

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 15

In the SAP system, you activate the SQL trace with transaction st05. The log is written by the database interface. Along with the statements, you'll find the variables, their values and the runtime. The Explain button in transaction st05 displays the database's Optimizer strategy for the command.

This transaction is discussed further in the section on SAP system transactions that are useful for error analysis.

The order interface of the database also writes an SQL trace. New versions of the WebAS ABAP kernel use the new interface SQLDBC instead of the Precompiler starting with version 6.20.

## ST05 – SQL Trace

You can use transaction st05 to activate an SQL trace. This is useful for performance analyses or for identifying a command that leads to incorrect result sets.

The SQL trace displays all SQL statements in the form in which they were sent to the database.

Note that when you use the button shown here, the trace must be deactivated before being displayed so that it can be formatted. You can display the trace directly by choosing *Performance Trace->Display Trace Or Deactivate First*

For a more manageable amount of information, you can restrict the display to a specific time period or a particular user or by omitting information about specified tables.

## ST05 – SQL Trace (2)

SAP

Transaction ST05		Work process no 0	Proc.type	DIA	Client	000	User	E30

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 17

The list of commands identifies which transaction was started, which work process is affected, its type, as well as the client and user.

The command list contains

- information about the duration of the command, where the long-running ones are marked red,
- the affected database object,
- the number of records found,
- the return code of the database and
- the statement.

The statement can be expanded by double-click. It is also possible to insert parameter values in the placeholders so that the statement can be used directly for further testing, for example in the SQL Studio.

The 'Explain' button displays the execution plan of the Optimizer.

SQL – Trace of the order interface:

## Profile parameter

■ dbs/ada/sql_trace =	0	no trace
	1	short trace
	2	long trace

## Environment variable

■ SQLOPT =	-F	file name
	-T	short trace
	-X	long trace
	-Y	statement count

## Itrace

- `itrace -p all -t <trace type>`
- `itrace -p <prozess-id> -t <trace type>`

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 18

The order interface trace is set for Disp+Work processes using a profile parameter. On Windows systems, after changing the profile parameter, only the work process has to be restarted. On Unix systems, the SAP system or the affected application server has to be restarted. The trace files are stored in the work directory of the SAP instance. The name is comprised of the process ID of the work process and the ending `.pct`.

Other tools that utilize the order interface read the environment variable SQLOPT. Unless otherwise specified with the -F option, the trace file is written to the current directory. The name is comprised of the name of the corresponding C module and the ending `.pct`.

You can use itrace to activate the trace without needing to restart the system/application server.

The tool gives you the following options for changing the trace:

- Activate/deactivate/switch trace for a particular process:  
`itrace -p <process id> -t <trace type>`
- The following trace types are available:  
long  
short  
off
- Activating/deactivating the trace for all interface processes on the application server:  
`itrace -p all -t <trace type>`

## Precompiler Trace (2)

Runtime library libSQLDBC for the development of database applications and interfaces

- Version-independent runtime library libSQLDBC.dll or libSQLDBC.so
- Version-dependent, e.g. libSQLDBC76.dll
- Runtime library libSQLDBC\_C.dll for the support of native C applications
- Stored in directory <indep\_program\_path>/pgm

Software Development Kit SQLDBC SDK

- Header file SQLDBC.h for C++
- Header file SQLDBC\_C.h for C
- Static and dynamic link libraries for C and C++
- Stored in directory <indep\_program\_path>/sdk/sqldbc

sqldbc\_cons

- Creation and control of traces

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 20

SQL Database Connectivity (SQLDBC) is a runtime environment for the development of database applications and database interfaces for MaxDB. Through SQLDBC, applications can access MaxDB database instances, execute SQL statements and edit data. SQLDBC is comprised of the three abovementioned components, which are part of the standard and stored in the said directories.

Traces can be created either directly with sqldbc\_cons or using transaction db50.

Configuration and creation of traces for the SQLDBC interface

Properties of the traces:

- sqldbctrace\_<pid>.prt
- The trace files are overwritten cyclically.

Traces storage in the following directories:

- <user\_home>\Application Data\sdb (Windows)
- <user\_home>/.sdb (UNIX, Linux)

Trace types:

- SQL: SQL statements (sufficient for most analyses)
- Short: method calls
- Long: method calls with call parameters (most comprehensive trace)
- Packet: communication packages

Syntax: sqldbc\_cons [<command>] [<option>]

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 21

sqldbc\_cons is a tool for the configuration and control of traces.

The trace files contain a file name of the form sqldbctrace-<pid>.prt, where <pid> is the process ID. It is also possible to choose a name; %p in the name is replaced by the process ID. Traces are stored in the directories <user\_home>\Application Data\sdb (Windows) and <user\_home>/.sdb (UNIX, Linux). When the configured trace size is reached, the trace is cyclically overwritten.

Possible commands for sqldbc\_cons:

TRACE SQL ON/OFF:	Turns the SQL trace on/off
TRACE PACKET ON/OFF:	Turns the PACKET trace on/off
TRACE SHORT ON/OFF:	Turns the SHORT trace on/off
TRACE LONG ON/OFF:	Switches the detailed LONG trace on/off
TRACE OFF:	Switches all SQLDBC traces off
TRACE FILENAME <file_name>:	determines the name of the trace file
TRACE SIZE <size>:	defines the size (in Bytes) of the trace file
SHOW ALL:	displays the configuration of the traces and current information about the traces
SHOW CONFIG:	displays the configuration of the traces
SHOW TRACESETTINGS	displays current information about the traces

Possible options for sqldbc\_cons:

- f: forces the execution of the command
- h: Help information
- p <pid>: executes the command only for the process with the process ID <pid>
- v: displays detailed information (verbose)  
(These options cannot be combined, but only used individually.)

The screenshot shows the SAP SQLDBC Trace application window. At the top, there's a toolbar with various icons. Below it is a menu bar with 'Goto', 'System', and 'Help'. The main area has tabs for 'SQLDBC Trace' (selected), 'Deactivate All Traces', and 'Activate All Traces'. Under 'Configuration', it shows the server as 'pwdt2763\_S70\_50', trace directory as 'd:\usr\sap\S70\DEVEMGS50\work\sqltrace-%p', and default size as '5'. It also lists 'Global Traces for All PIDs - Significant System Load' with options for 'SQL Trace', 'Long Trace', and 'Packet Trace' (all set to 'Switch on'). A 'STOP ON ERROR' button is also present. Below this is a table of 'Trace Files on d:\usr\sap\S70\DEVEMGS50\work' showing two entries: 'sqltrace-10256' and 'sqltrace-10132'. The main pane then displays 'Active Processes on Server pwt2763\_S70\_50' with a list of 11 processes, each with columns for Type, PID, Status, CPU, Time, User Names, Report, Action, Table, Name, Wait info, Time waiting for, and TraceType. At the bottom, there's a large text area showing SQL logs and error messages related to parsing and executing statements like 'SELECT 1 FROM DOMAIN\_TABLES WHERE OWNER = USER AND TABLENAME = ?' and 'SELECT 1 FROM DOMAIN\_TABLES WHERE OWNER = USER AND TABLENAME = ? AND ROWNUM <= 1'. The logs include details about parameters, columns, and specific errors such as 'Row not found'.

In transaction db50, choose the path *Tools-> SQLDBC Trace*.

Activating the trace involves three steps:

- Selection of the desired process
- Selection of the trace type (SQL, Short, Long, Packet)
- Specification of trace size (*Goto-> Maximum File Size*)

To switch the trace off, select the process and press the button *Switch off*.

Via menu item *Goto-> Trace Directory* you can choose a trace file name that differs from the default.

To display the trace, select the trace file and press the button *Display File*.

**Example 1:**

```
06.01 12:53:46 18286 -11205 sqlexec: system error, not enough space

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 23

The file **appldiag** contains error messages that can occur during communication between the applications and the runtime environment.

The file **appldiag** or **<pid>.dia** (SAP WebAS) is stored in the directory

<globaldatapath>/wrk/<unix user>	(UNIX)
<globaldatapath>\wrk	(Windows)
/usr/sap/<SID>/D*/work	(SAP WebAS)

The <globaldatapath> can be determined using the following dbmcli command:

```
dbmcli -d <SID> -u <dbm-user>,<password> dbm_getpath globaldatapath
```

(As of version 7.7 the appldiag can be found in the directory <indepdatapath>/wrk/<unix user>. The isolated installation had not been introduced in those versions.)

Under Windows, **appldiag** is only activated if the environment variable is set to DIAGFILE=yes.

The file **appldiag** can get very large since it is not cyclically overwritten.

If this file already exists, further messages are added to it; otherwise it is created.

The files **xserver\_<hostname>\_<port>.prt** contain error messages involving the communication via **x\_server**. x\_server are used for remote communication and start vserver processes for each new user who connects to the database remotely. When the isolated installation was introduced in 7.8 each server installation got an own x\_server with its own port.

If multiple database software versions (<= 7.7) are installed on a computer, the x\_server must always be started with the highest version.

You can display the highest version with

```
x_server -V
```

You can display the possible options for installing, starting and stopping with

```
x_server -h
```

If, f.e., there are network problems between the application and database server error messages are written to this log file.

The start information (see slide) contains additional information about operating system settings that are significant for database operation.

A time stamp, a process ID, in the label the affected software component and an explanatory message text are delivered.

If a return code is reported by the operating system, its meaning can be determined with

```
xsysrc <rc>
```

The **xserver\_<hostname>\_<port>.prt** are stored in the directory <globaldatapath>/wrk. The port can be determined with the following dbmcli command:

```
dbmcli inst_enum <InstallationPath>
```

Access via DB50: **Problem Analysis -> Messages -> Kernel – Remote SQL Server**

Access via Database Studio: **Diagnosis Files – XServer Messages / Xserver Messages (OLD)**

The Database Manager log **dbm.prt** comprises the command history of the Database Manager. All change actions and all actions that return error messages are logged.

Because messages show the exact date and time, they can easily be referenced against the outputs of other log files.

If errors occur in the action being executed, they are marked ERR.

The file is stored in the run directory (default: <indepdatapath>/wrk/<SID>).

Access via DBMGUI: **Check -> Diagnosis Files -> Database Manager Log File (DBMPRT)**

Access via DB50: **Problem Analysis -> Messages -> Database Manager**

Access via Database Studio: **Diagnosis Files – Database Manager Log File**

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 26

As of version 7.7 no special utility log file is written. The information is now written to the **dbm.prt**.

Up to version 7.6 all commands sent to the database kernel by the utility task are logged in the file **dbm.utl**. As of 7.5 user tasks executing utility statements also write into this file. The file is written by the database kernel.

This file contains detailed information about backup and restore processes, configuration changes such as the addition of volumes, information about update-statistics processes and so on.

In **dbm.utl** you can see whether operations have been successful from the point of view of the database kernel. When using external backup tools, it is important to take account of the corresponding log files as well, since errors can also occur on other levels during the transfer of backup information from the kernel to the tools.

The file is stored in the run directory of the database (default: <indepdatapath>/wrk/<SID>).

Access via DBMGUI: **Check -> Diagnosis Files -> Utility Statements (UTLPRT)**

Access via DB50: **Problem Analysis -> Logs -> Kernel Administration**

Access via Database Studio: **Diagnosis Files -> Utility Statements**

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 27

The file **dbm.knl** contains a list of the backup and restore actions that have been executed.

The file is written by the database kernel.

You can identify what type of backup (DATA, LOG) was executed, in which time period the execution took place, up to which log page number the data was backed up, which medium was used and whether any errors occurred.

When using external backup tools, it is important to observe their logs as well, which are described in the following pages.

The file is stored in the run directory (default: <indepdatapath>/wrk/<SID>).

Access via DBMGUI: **Information -> Backup History** or **Check -> Diagnosis Files -> Backup History (BACKHIST)**

Access via DB50: **Problem Analysis -> Logs -> DBA History -> Backup/Restore (Kernel)**

Access via Database Studio: **Diagnosis Files -> Backup History**

Because of the length of the output line, the file is somewhat difficult to work with; it is therefore a good idea to get a formatted display of the backup history with the Database Studio (Administration -> Backup) or transaction DB50. Errors are noted at the end of the output line.

The transactions DBACockpit (as of version 7.0), db12 and db13(c) use this information about backups to, for example, propose a recovery procedure.

## DB12 - Overview

SAP

The screenshot shows the SAP DB12 - Overview transaction screen. The title bar displays "DB12 - Overview". The menu bar includes "Logs", "Edit", "Goto", "System", and "Help". The toolbar contains various icons for database management tasks. The main area is titled "DBA Actions Logs: Overview" and contains three sections: "Data Backups", "DBA Actions", and "Memory Areas". The "Data Backups" section shows a last update timestamp of "10.09.2008 11:15:05" and a successful backup timestamp of "04.03.2008 10:17:37", with a "Display Log" button. The "DBA Actions" section has a "List of Logs" button. The "Memory Areas" section shows "Log Area" and "Data Area" buttons. At the bottom right, there is a SAP logo and status information: "A1S (1) 001 | Id1032 | INS".

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 28

SAP transaction db12 can be used to get an overview of backup and restore actions that have been executed.

Here you can also get information about the scope and frequency of Update Statistics operations as well as a history of consistency checks.

## DB12 – Overview

Screenshot of the SAP DB12 Database Administration Actions interface showing a list of backups and restores.

The interface includes a toolbar with various icons for database management tasks, a menu bar with DBA Actions, Edit, Goto, System, and Help, and a status bar at the bottom.

The main window displays a table titled "Backups and Restores (Kernel View)" under the "Backup/Restore (Kernel)" tab. The table has columns for Backup Label, Action ID, Error Co..., Start Date, Start Time, End Date, End Time, Number of..., Lo..., and Backup Template.

The table data shows several entries:

Backup Label	Action ID	Error Co...	Start Date	Start Time	End Date	End Time	Number of...	Lo...	Backup Template

At the bottom of the table, there are navigation buttons for first, last, previous, next, and search.

The status bar at the bottom right shows: SAP | A1S (1) 001 | Id1032 | INS |

Information from the file **dbm.knl** is optically presented which allows to recognize directly if there are failed backups or gaps in the backup history.

The output is generated when the DBM parameter DBATL is set to 1. For further information, see the Note **431508**.

The screenshot shows the SAP DB13 scheduling calendar interface. The main window displays a weekly calendar for July 2006, specifically week 28. The calendar grid shows various scheduled activities across the days of the week from Monday to Sunday. Some scheduled actions have red backgrounds, indicating errors or failed executions. A detailed view of one such action is shown in a floating window, titled 'Details zur Aktion' (Action Details), which specifies the action as 'Vollständige Datensicherung' (Full Database Backup) and its scheduled start time as '15.07.2006 03:00:00'. The interface includes a sidebar for 'Actions-Pad' containing a list of database maintenance tasks like 'Vollständige Datensicherung' and 'Inkrementelle Datensicherung'. At the bottom, a message indicates an action was added to the calendar.

db13 is the scheduling calendar for backups, Update Statistics runs and consistency checks. A weekly schedule can be used to plan the regular execution of activities.

Transaction DB13C is no longer required with WebAS 7.0 since transaction DB13 allows scheduling of activities for various instances. Integrate an instance with transaction DB59. Double-click to go to the database monitoring and via Tools -> DBA Planning Calendar to transaction DB13. Now the new instance will henceforth be known in transaction DB13.

Further information can be found in note **431508**.

It is also possible to call the scheduling calendar with transaction DBACockpit (Jobs -> DBA Planning Calendar).

If an error occurs during an action, it is displayed with a red background.

The causes of errors can be determined with the familiar diagnosis files. The job logs may also contain information that is useful in this regard.

## External Backup Protocol (dbm.ebp)

- Is created by each action using a supported backup tool.
- Is overwritten with every start of the DBM server, if it communicates with an external backup tool.

### Contents

- Configuration values
- Commands of the database kernel
- Call of the backup tools
- Returncodes of the backup tools and of the database kernel
- Output of the backup tools

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 31

For diagnosing problems with backups using external backup tools, the log file **dbm.ebp** plays a decisive role.

In addition to information about the configuration parameter of the tool, **dbm.ebp** contains information about the commands sent to the database kernel as well as the backup tool call. The error position makes it possible to identify who was responsible for the problem.

**dbm.ebp** is stored in the run directory of the database (default: <indepdatapath>/wrk/<SID>).

Access via DBMGUI: **Check -> Diagnosis Files -> External Backup Protocol**

Access via DB50: **Properties -> Files -> BACKEBP**

Access via Database Studio: **Diagnosis Files -> External Backup Protocol**

Note that this file is overwritten after each start of the DBM server when it communicates with the external backup tool. A new DBM server is started with each dbmcli call, to name one example.

## External Backup Log

- Contains a summary of the last <n> dbm.ebp files.
- The number is configurable.

```
2004-01-16 18:10:51 ----- Start of a new external backup tool action -----
2004-01-16 18:10:51 Setting environment variable 'TEMP' for the directory for temporary
files and pipes to default ''.
Setting environment variable 'TMP' for the directory for temporary files
and pipes to default ''.
Using connection to Legato's Networker with save, recover and mminfo.

2004-01-16 18:10:51
Checking existence and configuration of Networker.
  Setting environment variable 'NSR_ENV' for the path of Networker's
configuration file to default '/nsr/sapdb/env'.
    Found Networker setting for 'NSR_HOME': '/opt/nsr'.

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 34

The file **KnIMsg** contains messages of the database kernel. It is recreated each time the database instance is started. The previous file is renamed to **KnIMsg.old**. The messages - apart from the header (start messages) - are overwritten cyclically.

Error messages are recorded in **KnIMsg** but also - due to the risk that they will be overwritten there - in the file **KnIMsgArchive (knldiag.err)**. This file is written continuously.

As of version 7.7 **KnIMsg** files replace the files **knldiag\***. A specialty of the new files is that they are stored in an XML-like representation to make it possible in further states of expansion that together with the error messages directly instructions are delivered. This implies that the files – if you look at them on operating system level – have to be prepared before they can be displayed properly (see slide **protconv**). If you choose Database Studio, DBMGUI or transaction DB50 to display the **KnIMsg** the conversion to a readable format is done automatically.

The files **KnIMsg\*** are stored in the run directory of the database ((default: <indepdatapath>/wrk/<SID>). The size of **KnIMsg** can be changed by setting the parameter **KernelMessageFileSize**.

(In versions 7.5 and 7.6 location, size and name of the file can be changed with the setting for the parameters **\_KERNELDIAGFILE** and **KERNELDIAGSIZE**.)

Access via DBMGUI: **Check -> Diagnosis Files -> Database Messages**

Access via DB50: **Problem Analysis -> Logs -> Kernel Administration**

Access via Database Studio: **Diagnosis Files -> Database Messages**

Examples:

```
protconv -d A1S -t KNLMSGARCHIVE -o KnlMsgArchive.prt
protconv -p /sapdb/data/wrk/A1S -t KNLMSGOLD
```

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 37

The tool **protconv** (with the options shown below) is provided to allow access to the **KnlMsg** on operating system level in a readable form. If no output file is specified the text is shown directly on the screen. You can use KNLMSG, KNLMSGOLD and KNLMSGARCHIVE als filekey (tag).

**protconv -help**

```
Usage: [-h [[<Option> | LONG]]] [-? [[<Option> | LONG]]] [-d <DBName>]
      [-o <OutputFile>] [-f <OutputFormat>] [-t <FileKey>]
      [-p <InputFilePath>] [-s <SortMode>] [-v] [-b <TimeStamp>]
      [-e <TimeStamp>]
```

-h <...>	- help
-? <...>	- help
-d <DBName>	- name of the database
-o <OutputFile>	- output file
-f <OutputFormat>	- output format (classic plain(default) xml)
-t <FileKey>	- file key
-p <InputFilePath>	- path to read input files from
-s <SortMode>	- sort mode (!ignored!)
-v	- display message description from supplied files
-b <TimeStamp>	- output messages that were written after this time stamp only
-e <TimeStamp>	- output messages that were written before this time stamp only

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 38

When the database crashes, support often needs to know at which point in the source code the database was when the crash occurred.

On Unix/Linux, this information is usually generated from a core dump with a debugger. On Windows, this information is found in the file drwtsn32.log, but only if Dr Watson is registered as the system debugger.

Core dumps can be very large. Writing a core dump delays the crash of the process.

For that reason, when a crash occurs the MaxDB kernel automatically writes the backtrace stack and values of the CPU register to the ***KnIMsg (knldiag)*** file.

If the problem is due to an error in the database software, the cause can usually be found using this information.

In the present example we see a simulation of an I/O error during writing to a log volume. It is not a software error.

## Event Viewer

Under WINDOWS important messages are additionally written to the event log.

Example:

The screenshot shows the Windows Event Viewer application. On the left, the 'Application Log on \\P28121' is selected. A context menu is open over an error event from 'ADABAS:Db629'. On the right, the 'Event Detail' window is displayed, providing detailed information about the event. The event details are as follows:

Date	Time	Source	Category	Event
15.02.99	15:29:33	Sappui	None	42
15.02.99	14:53:46	ADABAS:Db629	Fast	18144
15.02.99	14:49:58	ADABAS:Db629	Fast	18144
15.02.99	14:32:09	ADABAS:Db629	Fast	18144
15.02.99	13:58:16	ADABAS:Db629	Fast	18144
15.02.99	13:33:30	Sappui	None	42

15.02.99	10:09:38	liveCache:Lca	Fast	18239
15.02.99	10:09:34	liveCache:Lca	Fast	19083
15.02.99	10:09:34	liveCache:Lca	Fast	19081

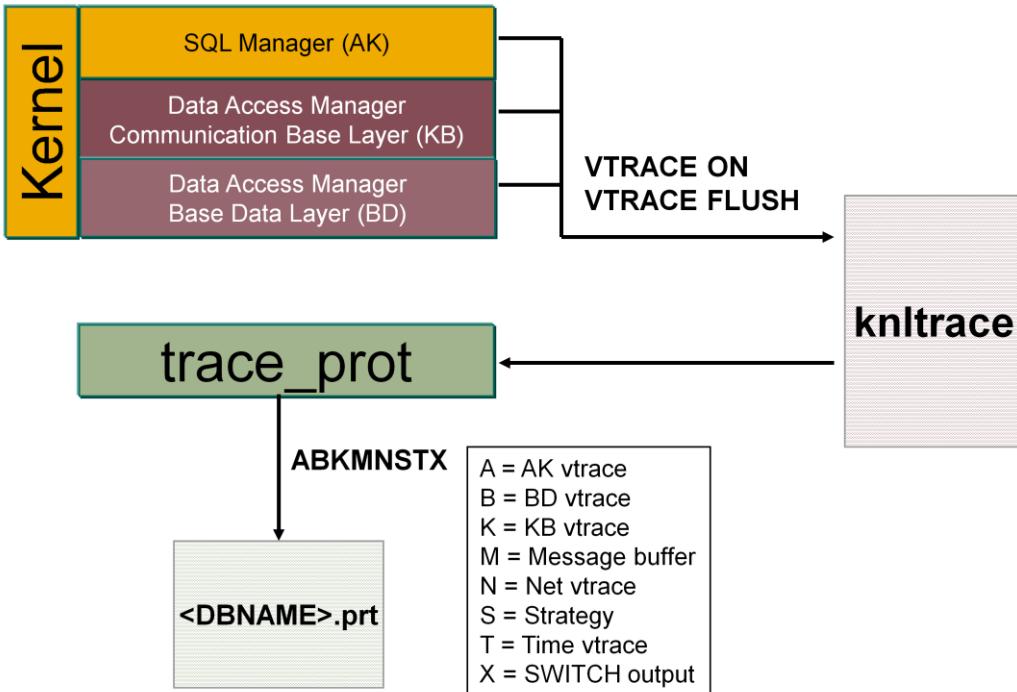

**Description:**  
ADABAS - Db629:  
- ERROR TID: 0x11E PID: 0x153 MsgID: 18144  
Devspace 'C:\DB629\LOG', position 2082 was marked as bad

Buttons at the bottom of the 'Event Detail' window include Close, Previous, Next, and Help.

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 39

If the file **KnlMsg** has already been overwritten, you may still find useful information here.

## knltrace (1)

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 40

The kernel trace, or Vtrace, is used for analyzing executed SQL statements.

When you activate Vtrace, you specify which areas of the kernel the file **knltrace** is written from. Generally a default setting is taken.

The kernel trace is not active by default. The default trace has a minimal effect on system performance. Each UKT writes to its own main memory buffer, precluding collisions during trace writing. If you select other options, however, writing the trace can be resource intensive and should be done only where needed for problem analysis.

For the trace output, you specify the levels or modules of the kernel for which the logs are to be extracted.

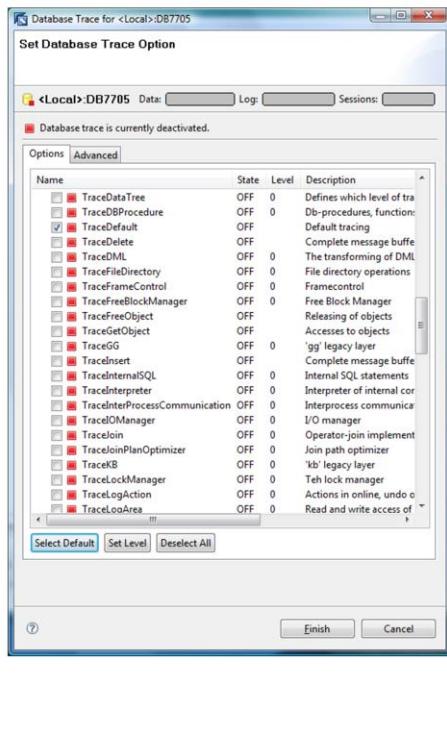

Data concerning strategies and times is only output if the options OPTIMIZER or TIME, respectively, are active for the Vtrace.

The SWITCH output contains data from the trace of a so-called slow kernel. A slow kernel is a special MaxDB debugging kernel. It is only used upon the special request of development or support.

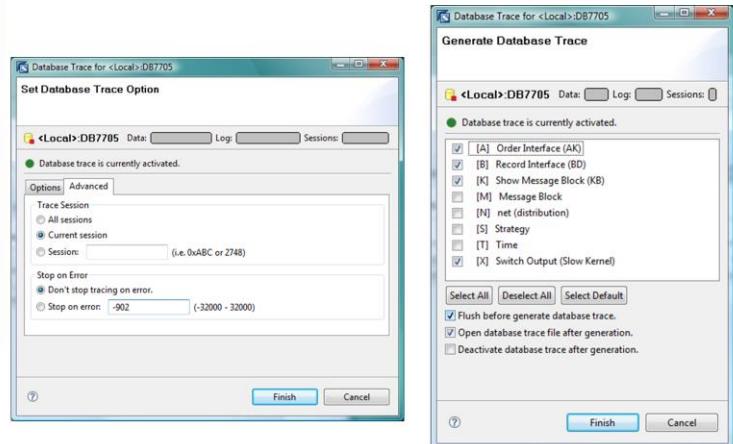

The Vtrace can be activated for a single user session (FOR SESSION).

To prevent cyclical overwriting, the writing of the trace can be switched off automatically when a specified error code occurs (STOP ON ERROR).

## knltrace (2) - Procedure

1. Switch on the VTRACE  
(if required for a specified session)
2. Execute database action
3. VTRACE FLUSH
4. Switch off the VTRACE
5. Convert the file to ASCII format

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 41

Switching the Vtrace on or off as well as flushing it can be done with the dbmcli, the Database Studio or DBMGUI and with transaction db50. Flushing the Vtrace can also be done with the SQLSTUDIO.

Required dbmcli commands:

Activate:

```
dbmcli -d <SID> -u <dbm-user>,<password> trace_on default
```

Flush:

```
dbmcli -d <SID> -u <dbm-user>,<password> trace_flush
```

Deactivate:

```
dbmcli -d <SID> -u <dbm-user>,<password> trace_off
```

Evaluate:

```
dbmcli -d <SID> -u <dbm-user>,<password> trace_prot <options>
```

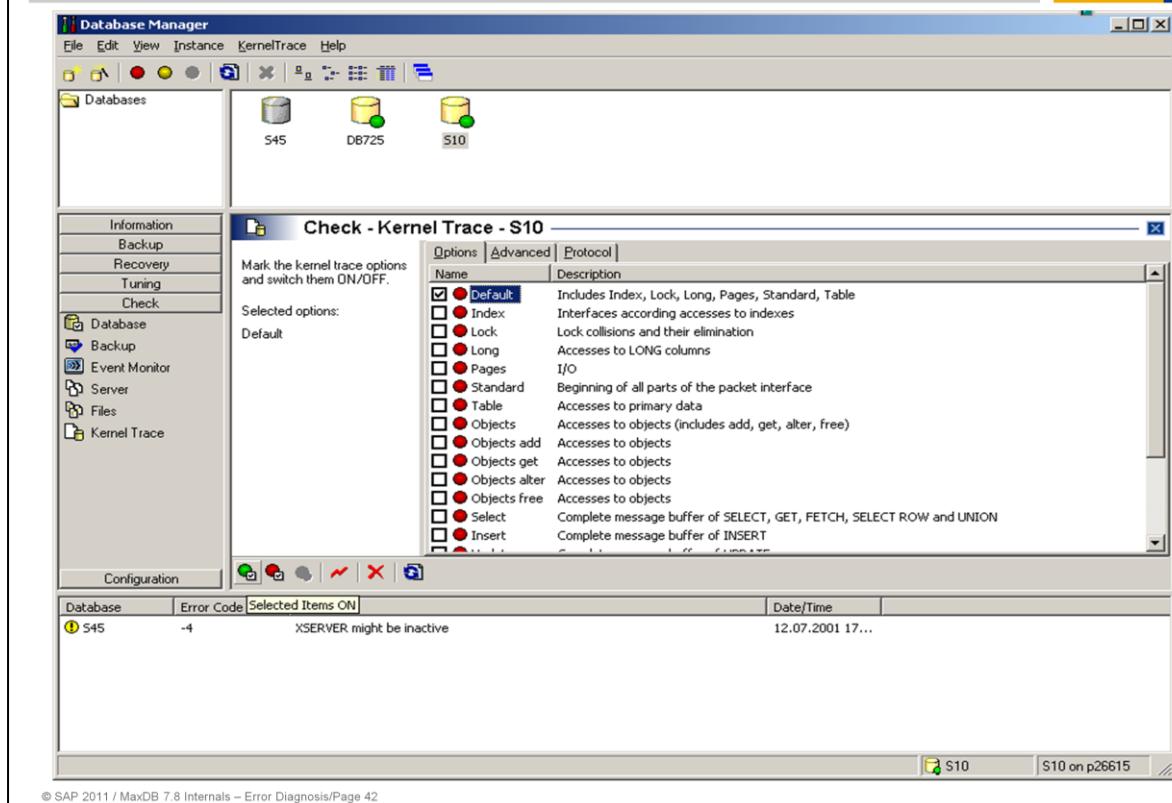

In the context menu of the installed databases the trace can be switched on and generated as a readable file with.

Database Trace -> Options

Database Trace -> Generate

# DBMGUI Kernel Trace (1)

SAP

You can administer the database kernel trace with the DBMGUI.

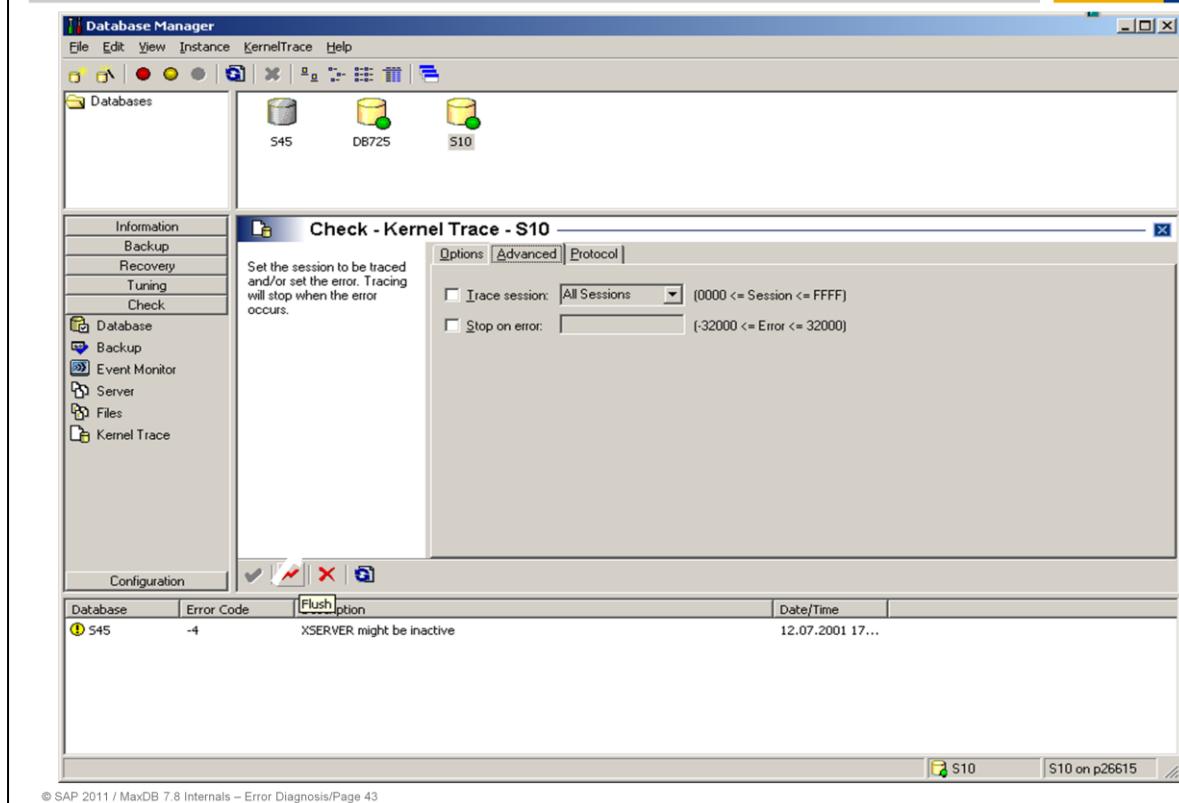

Unless otherwise specified by development or support, the default Vtrace is sufficient.

You can also activate information about DELETE, INSERT, UPDATE, SELECT and Optimizer operations.

The Vtrace can be activated and deactivated, flushed, initialized and displayed using the buttons. During initialization, all information in the trace buffer is deleted.

## Kernel Trace (2)

SAP

### TRACE SESSION

The Vtrace can be activated for particular database sessions. To do so, however, the database session must be known.

The outputs of

**x\_cons <SID> show active** and  
**SELECT \* FROM TRANSACTIONS**

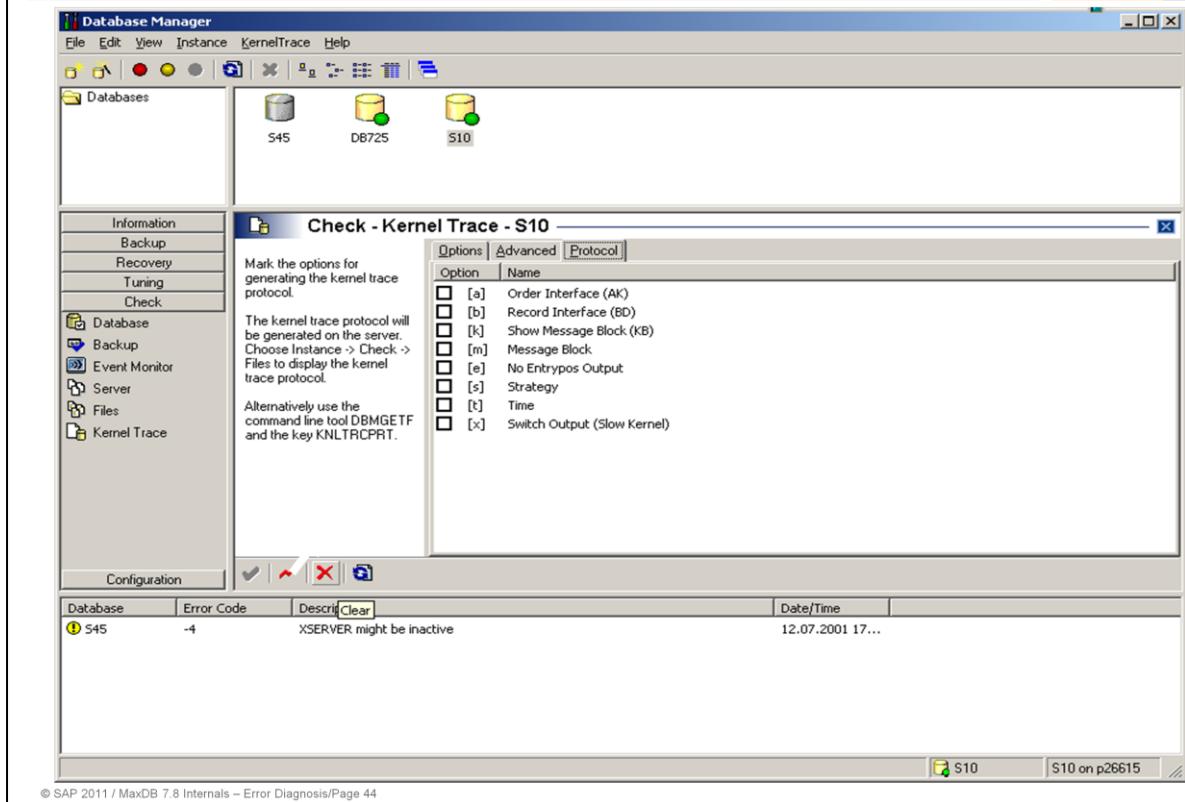

are helpful in this regard.

### STOP ON ERROR

You can set the Vtrace so that it is automatically switched off when a certain error occurs. This is useful when you want to reproduce a particular problem and know which error will occur. This function prevents relevant information from being overwritten.

## Kernel Trace (3)

SAP

On the '**Protocol**' tab, you can sort the information from the **knltrace** file and extract desired areas to an ASCII file.

You specify the layers or modules of the kernel for which you want to extract the trace outputs;  
DEFAULT: abkmx.

Data concerning strategies and times is only output if the options OPTIMIZER or TIME, respectively, are active for the Vtrace.

The SWITCH output contains data from the trace of a so-called slow kernel. A slow kernel is a special MaxDB debugging kernel. It is only used upon the special request of development or support.

## Kernel Trace (4)

The screenshot shows the SAP Database Manager interface. On the left, a sidebar lists various maintenance tasks: Information, Backup, Recovery, Tuning, Check, Database, Backup, Event Monitor, Server, Files (which is selected), and Kernel Trace. The main pane displays a terminal window titled "Check - File - S10 - Kernel Trace Protocol" with the timestamp "13.07.2001 10:35:53". The window contains a trace log from the KERNPROT 7.2.5 protocol, dated 2001-07-13 09:34:35. The log details a sequence of database operations, including an RECEIVE command and a REQUEST command. Below the terminal window is a table titled "Configuration" with one row showing an error for database S45 with error code -4 and description "XSERVER might be inactive". The bottom status bar indicates "S10" and "S10 on p26615".

You can display the contents of the Vtrace via the menu path ,**Check -> Files -> Kernel Trace Protocol**'

Even if you can find the evaluated error using the search function, it is all but impossible for a customer to form an independent interpretation of this trace. Errors can be found here only with knowledge of the source code. Thus the trace file should be provided to development.

# DB50: Problem Analysis – Kernel Trace (1)

The screenshot shows the SAP MaxDB Database Trace interface. On the left, there's a navigation tree under 'A1S' with sections like Properties, Alert Monitor, Current Status (Activity Overview, Configuration, Kernel Threads, I/O Operations, Memory Areas, System Settings, Critical Regions), Problem Analysis, Statistics, Administration, Tools (Database Manager (GUI), Database Manager (CLI), SQL Studio, Database Console, Database Trace, SQLDBC Trace, DBA Planning Calendar). The main panel has tabs: Switch Trace On/Off, Set Extended Options, Evaluate/Display Trace. Under 'Set Extended Options', there's a table of trace components with columns: S, Stat., Component, L..., Description. Some components have checkboxes (e.g., TRACE\_DEFAULT, TRACE\_INSERT, TRACE\_LOCK, TRACE\_OBJECT, TRACE\_OBJECT\_ADD, TRACE\_OBJECT\_ALTER, TRACE\_OBJECT\_FREE, TRACE\_OBJECT\_GET, TRACE\_OPTIMIZE, TRACE\_ORDER, TRACE\_ORDER\_STAND, TRACE\_PAGES, TRACE\_PRIMARY\_TREE, TRACE\_SELECT, TRACE\_TIME) which are checked. Other components are radio buttons (e.g., CHECK\_HASHED\_RESU, TRACE\_AK, TRACE\_DELETE, TRACE\_LOB). The 'Description' column provides details for each component. At the bottom right of the main panel, there are buttons for Trace On (Lev...), Trace Off, Init Trace, and a status bar showing A1S (1) 001 | Id1032 | INS.

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 46

Administering the kernel trace (vtrace) can also be done with transaction db50.

**Initialize Trace:** If you want to be sure that only subsequent database actions are logged, choose '**Init Trace**'.

**Activate Trace:** To activate the trace, first choose your trace options, (usually default options) and then '**Trace On**'.

You can activate more trace options while the trace is running by selecting them and choosing '**Trace On**' again.

Then the program that received the short dump, for example, is restarted.

The "Status" column shows whether the trace is currently activated, and with which options. The activated options are displayed in green.

## DB50: Problem Analysis – Kernel Trace (2)

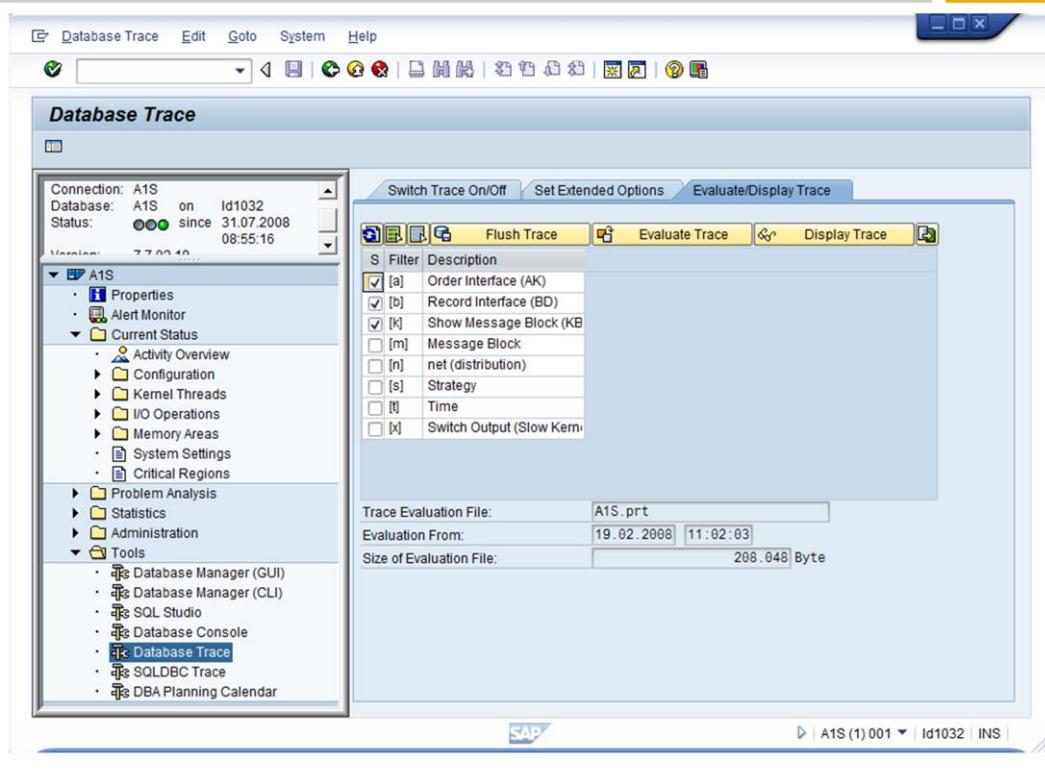

The screenshot shows the SAP Database Trace application window. The left pane displays connection information (Connection: A1S, Database: A1S on Id1032, Status: 000 since 31.07.2008 08:55:16) and a tree view of tools under A1S, with 'Database Trace' selected. The right pane contains tabs for 'Switch Trace On/Off', 'Set Extended Options', and 'Evaluate/Display Trace'. The 'Set Extended Options' tab is active, showing options for activating and deactivating the trace. Under 'Activate Trace', 'For All Sessions' is selected. Under 'Deactivate Trace', 'Manually Only' is selected. A 'Save Options' button is also present.

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 47

On the '**Set Extended Options**' tab, you can determine whether the kernel trace should be written only for a selected session and whether it should be stopped automatically in case of a selected error code in order to prevent overwriting.

## DB50: Problem Analysis – Kernel Trace (3)

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 48

When the program you want to check has been terminated, the Vtrace has to be flushed so that the information in the buffer is written to the disk.

**Flush Trace Buffer** : To analyze the trace, choose '**Flush Trace**'.

**Format Trace** : To format the trace to a legible form, first select the desired layers and then '**Evaluate Trace**'

## DB50: Problemanalyse – Kernel Trace (4)

The screenshot shows the SAP MaxDB 7.8 Internal - Error Diagnosis interface. The main window title is "Ausgabe einer Datei". The left sidebar shows a tree view of database connections and tools, with "Datenbank-Trace" selected. The right pane displays a text log of a kernel trace. The log starts with "==== T526 ===== idn11 ===== 7.7750 page 8" and contains numerous lines of assembly-like code representing database operations. The SAP logo is visible in the top right corner.

```
===== T526 ===== idn11 ===== 7.7750 page 8

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 40

**Display Trace**: Immediate display can be effectuated with '**Display Trace**'.

As the resulting file <SID>.prt can attain a considerable size, you can use the right-hand button to save to a local file.

The extracted trace is then read and analyzed by support and development. Knowledge about the source code is required for further interpretation.

Contains the global memory, e.g.:

- Lock lists, data cache, catalog cache, ...
- Administration structures of these caches

The file is created in the following ways:

- DIAGNOSE: by a user with DBA rights
- dbmcli: db\_stop –dump
- when the database crashes

The file ‘knldump’ might become very huge. It contains binary data which can be transferred to a readable form with DIAGNOSE.

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 50

In case of crash or hang situations due to manual interventions, the database generates a dump that contains the information from the global memory.

UNIX: No dump is written if the database crashes due to a UNIX signal.

The file **knldump** is stored in the run directory of the database ((default: <indepdatapath>/wrk/<SID>).

If there's not enough space in the filesystem here, for example, you can change the location and name of the file with the parameter KernelDumpFileName (\_KERNELDUMPFILE).

As this is a binary file, displaying it with the Database Studio, DBMGUI or transaction db50 is not useful.

As default the parameter AbortHandlingMode is set to BacktraceOnly. This has the effect that MaxDB does not write a knldump in case of a crash; the output of a core file is also suppressed.

## rtedump (1)

Status of the runtime environment in case of crash

- `x_cons <SID> show all`
- helps to identify previously active tasks
- detailed information about the individual tasks
- region statuses, suspend reasons, counter statistics

Additional analysis for KnIMsg output

No formatting necessary (legible file)

Storage in run directory

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 51

If a crash occurs, the status of the runtime environment is recorded in an **rtedump**.

The data corresponds to that in the output of `x_cons <SID> show all`

The file can be viewed directly in a system editor; no further formatting with a tool is required.

The file **rtedump** is stored in the run directory of the database ((default: <indepdatapath>/wrk/<SID>). Location and name of the file can be changed with the setting for the parameter RTEDumpFileName (\_RTEDUMPFILE).

Access via Database Studio: **Diagnosis Files -> Runtime Environment Dump**

Access via DBMGUI: **Check -> Diagnosis Files -> Runtime Environment Dump (RTEDUMP)**

Access via DB50: **Properties -> Files -> RTEDUMP**

## rtedump (2)

### Example:

- Identification of the active task (status "Running")
- Detailed information about this task
- Identification of the affected application server
- If necessary, additional information in the system log as well as in the dev log tell you more about the triggering command.

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 52

In addition to the information from **KnIMsg (knldiag)**, the output of **rtedump** can be of use in analyzing crashes. This can be the case for a variety of reasons as this dump contains a plethora of information from the runtime environment. But these special cases will not be discussed further here.

An example is shown on the slide. **rtedump** can help identify the command that caused a crash by determining the tasks that were active at the time. They are in the `x_cons <SID> show task` part of the output and marked "Running". In the detailed information for each individual task you'll find the application server under "remote\_node". In the system log or the dev logs of this application server, commands are logged that led to some problem. Even if it cannot be guaranteed that the identified command was solely responsible for the crash, it is still worthwhile to try to reproduce the crash and (for instance with activated traces) determine the cause of the error.

Dump of corrupt pages

- Checksum error: \*.bad
- Problem with page content identified: \*.cor

Storage in run directory

Formatting done with `x_diagnose`

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 53

If corrupt pages are identified, they are written to the file system so they can be subjected to further analysis.

A corrupt page is dumped as a \*.bad file if the I/O check found an error while importing a page (checksum error).

A \*.cor file is generated if a content problem is identified with the available context knowledge while working with a page in the cache.

The files are generated in the run directory of the database ((default: <indepdatapath>/wrk/<SID>).

As these are binary files, display with Database Studio, DBMGUI or transaction db50 is not useful. Evaluation is done with the tool `x_diagnose`.

# Database Studio – Access to Diagnosis Files

The screenshot shows the SAP MaxDB Database Studio interface. The main window title is "Database Studio - <Local>:DB7705 - Database Manager Log File - SAP MaxDB Database Studio". The left sidebar shows a tree view of "My Repository" and "Servers" (including <Local>, DB75, DB7500, DB7605, DBM, and DB7705). The central pane displays the "Database Errors (xml)" content for the selected database. The errors listed are:

Line Number	Text
2 ..	0x00001058 ERR 10 DBMKnl Returncode: -902
2 ..	0x00001058 ERR 5 DBMKnl ErrorText: I/O error

The bottom status bar shows the path "/World/Local/My Landscape/Serv...iles/Database Manager Log File" and the connection details "Local".

With Database Studio you can access via context menu for the selected database to the presentable diagnosis files. Binary files like Database Dump (knldump) or Database Trace (Raw/Binary) cannot be displayed without former evaluation. The Kernel Messages (KnlMsg) files stored in XML format are directly shown in a readable form.

# DB50 – Access to Diagnosis Files

The screenshot shows the SAP GUI interface for transaction DB50. On the left, there's a navigation tree under 'Properties' for connection A1S. The tree includes sections like 'Current Status', 'Problem Analysis', 'Administration', and 'Tools'. Under 'Tools', several options are listed: Database Manager (GUI), Database Manager (CLI), SQL Studio, Database Console, Database Trace, SQLDBC Trace, and DBA Planning Calendar. On the right, a table titled 'File Overview' lists various diagnosis files with their details:

File ID	File Name	Size	Date	Time	Description	FileType
KNLMSG	KnlMsg	8.447.051	16.09.2008	10:47:38	Database Messages	ASCII
KNLMSGARC	KnlMsgArchive	1.470.464	12.09.2008	02:59:24	Database Errors	ASCII
KNLMSGOLD	KnlMsg.old	8.450.269	26.07.2008	05:06:50	Database Messages (OLD)	ASCII

With SAP transaction db50, error diagnosis can be performed for a running (online) database using the SAPGUI. Which tool you use is a matter of personal preference; however, this redundancy is often useful, for instance if only certain activity types or not all passwords for the various access types are available to you.

db50, then, also allows simple access to all diagnosis files of the database via the menu option *Properties* and the *Files* tab. Here you see an unarranged list; the actual contents of the most important diagnosis files are still located on the various menu paths.

Using transaction db59, you can administer multiple MaxDB and liveCache instances from a SAP WebAS.

As of WebAS version 7.0 the transaction DBACockpit can be used as a central tool for database administration. In addition to several administrative tasks that are also provided by transaction db50, in the cockpit the planning calendar is maintained. Backup activities, update statistics and consistency checks can be scheduled here.

```
Command Prompt - telnet p34777

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 57

**dbmcli** is used for line-based database administration work; the name is an acronym for Database Manager Command Line Interface.

It can be useful for short ad hoc queries in a telnet session or for use in scripts. For more extensive administration tasks, the DBMGUI is preferable as it initiates the action and does not require precise knowledge of the command sequences, which can be very complex.

Commands are sent to the DBM server, which processes the requests; the commands that have been sent are logged in the file **dbm.prt**.

The **dbmcli** allows you to open a utility or an SQL session, which means that SQL queries can be sent to a database in the online operational state. The utility session is meaningless and only exists because of compatibility reasons.

The **dbmcli**, as the illustration makes clear, has an extensive range of functions. You can display the list of possible commands in a dbmcli session with **help**. The help information contains additional information about which parameters have to be entered and what type of logon is required.

Some commands cannot be used alone, but only make sense as part of a command sequence.

## dbmcli - Examples

```
OK
State
ONLINE
p34777:e30adm 56> dbmcli -u control,control -d E30 dbm_getpath IndepDataPath

p34777:e30adm 63> ■
```

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 59

The examples show some commands that are useful for diagnosis; these are stand-alone commands that can provide an initial overview of the situation.

In command 60, in addition to logging on with the DBM operator, you must also specify a user authorized to access database objects.

## dbmgetf

The screenshot shows two separate Telnet sessions. The top session is titled 'Telnet Id1032' and displays the help documentation for the dbmgetf command. The bottom session is also titled 'Telnet Id1032' and lists various log files (KnlMsg files) with their abbreviations and corresponding full names.

```
1d1032:a1sadm 51> dbmgetf - help
usage: dbmgetf [<options>]
<options>:
  -d  dbname      (name of database)
  -u  user,pwd   (user for authorization)
  -U  userkey    (userkey for authorization)
  -n  node        (name of servernode)
  -e  encryption  (encryption method)
                (use only with -n)
                (valid methods: 'SSL')
  -k  id          (id of database file)
  -f  file        (name for local file - optional)
  -q              (quiet mode)
  -l              (list file id's)
  -p  <param>    (DATE or LINE parameter)
  -op <opid>     (SHRINK or DELETE operation)

1d1032:a1sadm 71> dbmgetf -U c -d A1S -l
KNLMSG
KNLMSGARC  ...
KNLMSGOLD  INSTPRT
KNLTRC     KNLTRCPRT
BACKHIST   DBAHIST
BACKMDF    DIAGDIR
DBMPRT    ANALYZER
DBMMDF    LCTRCH#init.log
DBMPAHI   LCTRCH#init.his
LCINIT    EDCFGI
LCINITCMD ...
LCINITTHIS ...
```

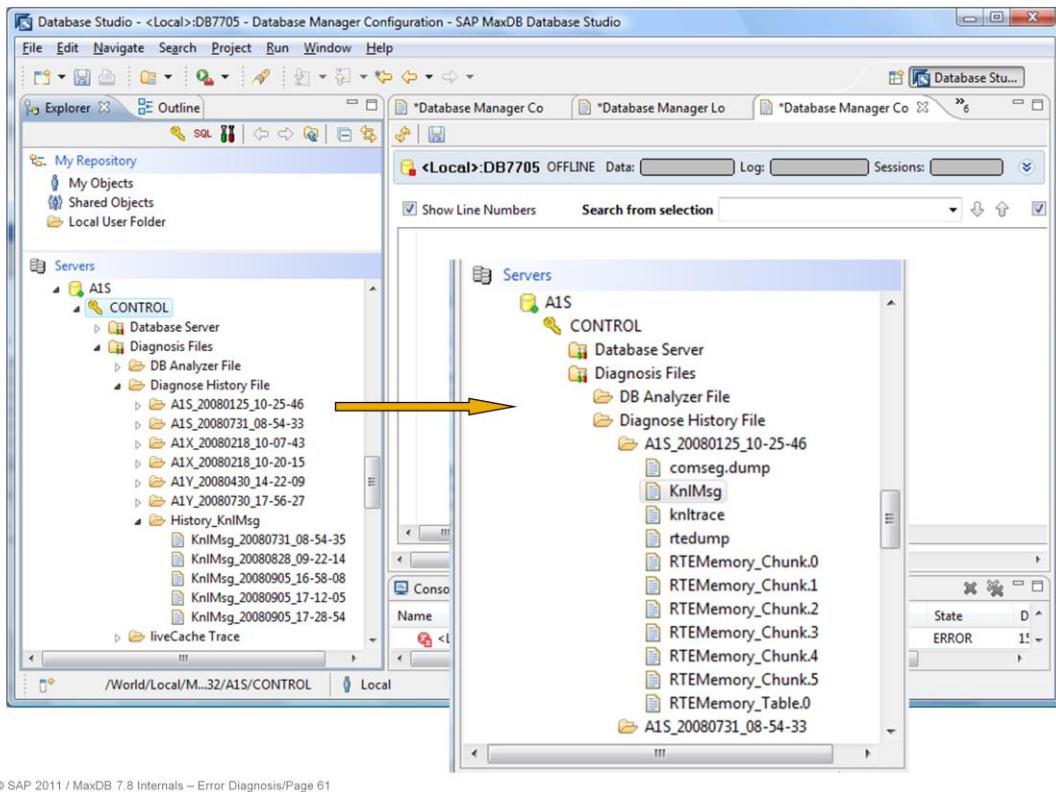

**dbmgetf -d A1S -u control,control -k KNLMSG**  
**dbmgetf -n p34777 -d E30 -u control,control -k DBMPRT**

**dbmgetf** is a tool that enables quick access to log files, for instance in a telnet session. It is mainly used internally since, in general, the GUI-supported display options are more convenient. The KnlMsg files are automatically transformed to a readable format.

With the -n option, you can specify a computer on which you want to enable remote access.

The log files are not addressed by the names stored in the operating system, but rather by abbreviations, which can be displayed using the -l option.

# DIAG\_HISTORY

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 61

There is an automatic procedure for receiving important information about crash situations.

The following files do not have to be explicitly backed up after a crash since they are automatically copied to a backup directory:

KnlMsg (knldiag), knltrace, knldump, rtedump, \*.dmp, \*.buf, \*.stm

If the database recognizes that it is being restarted after a crash, then the necessary files are backed up to a directory with the following naming convention:

- <DB-NAME>\_<DATUM>\_<ZEIT>, e.g.: S10\_20001114\_12-09-45

The backed up diagnosis files are deleted from the original directory.

The backup directory is under the directory **DiagnoseHistoryPath (DIAG\_HISTORY\_PATH)** (which must be configured) and is referred to as the history in the following.

You can also configure the number of histories with parameter **DiagnoseHistoryCount (DIAG\_HISTORY\_NUM)**. If you exceed this number of histories, then the oldest history is deleted when a new backup is made.

The database can still be restarted if a backup cannot be made correctly.

## CHECK DATA [Options]

- Checks structural consistency of the whole database. If no errors are found, „bad flags“ in the so-called filedirectory and the root page are reset.

## CHECK TABLE <OWNER>.<TABLENAME> [Options]

- Checks all pointers within the specified table tree.

### Mirroring

- If data volumes are mirrored by means of the operating system or by hardware, the database cannot influence which disk is used for reading pages. CHECK TABLE may not find any errors.

### Errors

- If CHECK TABLE delivers an error, hardware problems must be solved and a backup must be restored.

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 62

**Check Data** (previously Verify) checks the structural consistency of the entire database. It considers tables as well as indexes and LOB columns.

The semantics of the data model is not taken into account. Logical errors are not found, but only errors caused by hardware defects.

Every page contains a check number. This is calculated with each read-I/O and compared with the value stored on the page. If the values are different, there is an error.

One typical error that may be detected is BAD DATA PAGE.

**Check Table** checks all dependencies and links within the specified table tree. Indexes are not taken into account.

### CHECK DATA

- EXTENDED

Extended check of the key sequence

- EXCEPT INDEX

Indexes are not checked

- WITH UPDATE

Execution in DB mode ADMIN

Additional maintenance of the converter: page numbers with no references are removed.

### CHECK TABLE

- WITH LONG CHECK

Additional check of LONG columns

Share lock is set

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 63

Another diagnosis option is calling

#### **CHECK DATA EXTENDED.**

This performs a more precise check of the key lengths and checks the sequence of the primary keys on all levels of the B\* tree. Because this option is CPU-intensive, execution was not standard in older versions. As of version 7.6.01 it is standard behaviour for CHECK DATA and CHECK TABLE, because CPU load can now be neglected due to the performance of modern CPUs.

The option **WITH LONG CHECK** makes an additional check of BLOBs. As the name in older releases suggests, a lock is set on tables while the command is executed.

To save time when checking the database, you can use the option **EXCEPT INDEX**. Secondary indexes are not checked in that case.

## Consistency Checks (1)

- Transactions DBACockpit, db13
- dbmcli: db\_execute check data
- Check Table (f.e. via transaction db50 -> Tables/Indexes)

The screenshot shows the SAP DBACockpit interface. A table named 'ATAB' is selected. The 'Properties' tab is active, displaying information such as Type (TABLE), Access Rights (SEL+UPD+DEL+INS+REF+IND+ALT+), and creation date (24.01.2008). There is also a 'Table Consistency' button.

The screenshot shows the 'Aktion einplanen' dialog box. Under the 'Aktion' section, the radio button for 'Check database structure (all objects)' is selected. Arrows point from the 'Check database structure (all objects)' option in the list to both the 'Check database structure' entry in the 'Action Pad' and the 'Check database structure (all objects)' entry in the 'Action Pad'.

The screenshot shows a Command Prompt window with the following output:

```
DBMCLI on DB75>db_execute check data
OK

DBMCLI on DB75>db_execute check table superdba.sysmonitor
OK
```

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 64

The screenshot shows the 'Action Pad' on the right side of the SAP DBACockpit. It lists several actions, with 'Check database structure' highlighted by a yellow arrow. Arrows also point from the 'Check database structure' entry in the 'Action Pad' to both the 'Check database structure (all objects)' option in the dialog and the 'Check database structure' entry in the 'Action Pad'.

The structural consistency of the database can be checked in different ways.

If you choose '**Check database structure (all objects)**' transaction db13, all B\* trees, including indexes, are checked. ,**Check database structure (only tables)**' checks only the tables.

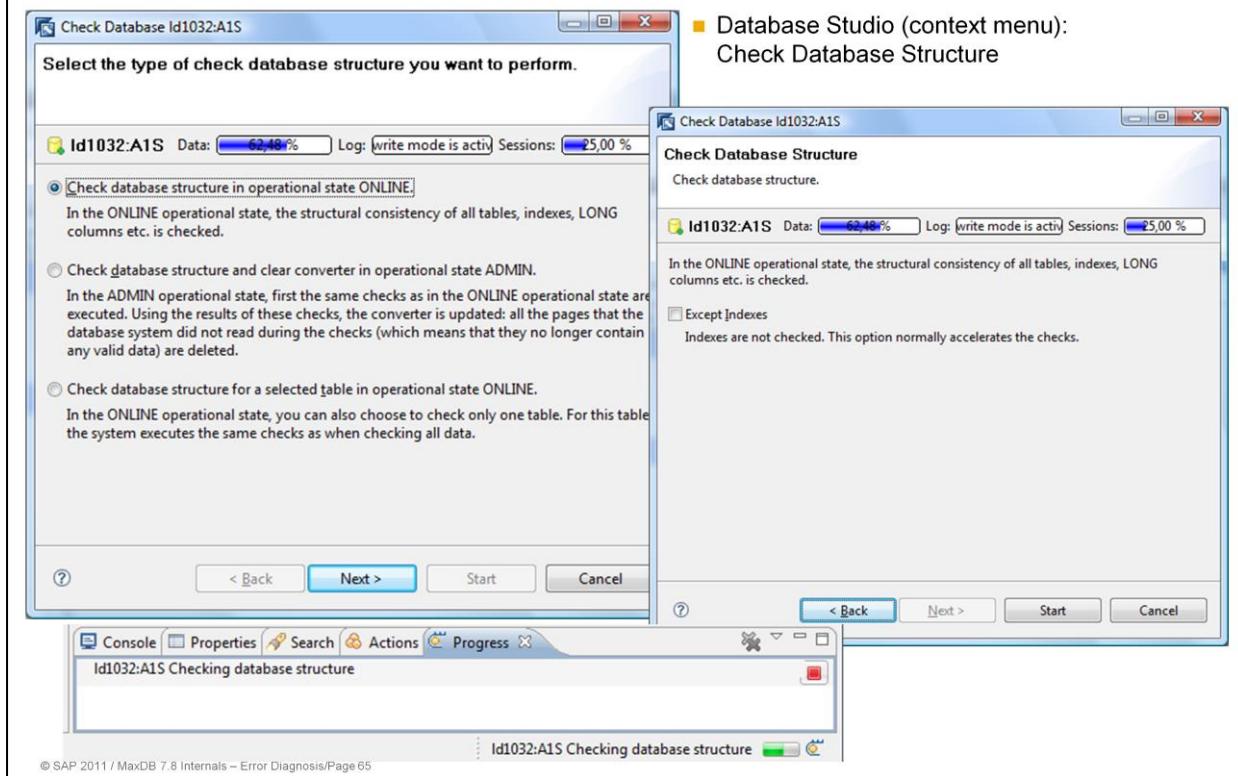

You can also start consistency checks with the dbmcli:

- dbmcli > db\_execute check data (checks all tables and indexes)

- dbmcli > db\_execute check table <owner>. <tablename> (selection of a table)

Transaction db50 enables you to select a table for which ,*Check Table*' (see next slide) is then initiated.

## Consistency Checks (2)

In Database Studio choose ,**Check Database Structure**' in the context menu of the database. There are different choices.

A consistency check can be executed in different operational states of the database. In ONLINE state the structural consistency of all tables, indexes and LOB columns is checked. In ADMIN mode additionally the converter is updated; pages with no more references are deleted.

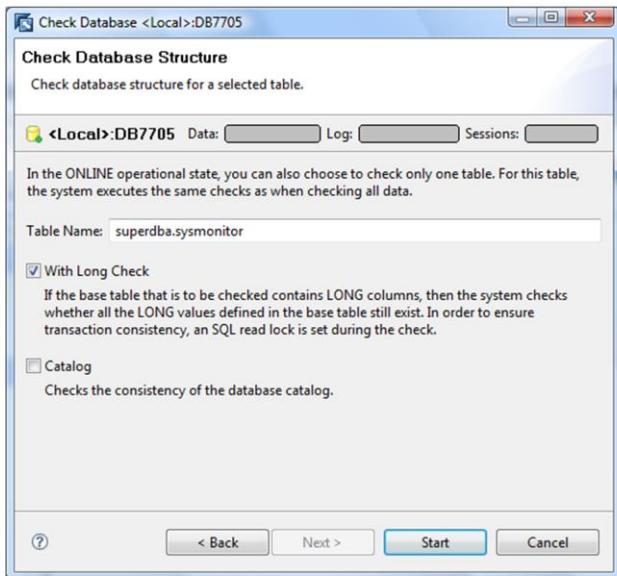

The check can be restricted to one table.

The amount of data to be checked can be restricted with the option ,Except Indexes'. As of version 7.6.01 an EXTENDED check is automatically done; so there is no more need for the database studio to provide this as an option.

Database Studio shows in the status information (Progress) that a CHECK DATA is executed right now. There is no feedback given if the execution was successful. In case of errors a popup is shown describing the first error.

A check of the database structure is time-consuming and CPU-intensive. For a productive system the check should be planned for times of low workload (f.e. on weekends) or. if possible, the check should be done on a separate system copy.

## Consistency Checks (3)

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 66

The check can be restricted to a specified table.

With **CHECK CATALOG** the catalog information of a chosen table can be checked.

## Consistency Checks (4) – Check Success

### ■ dbm.prt

```
2004-11-30 11:11:31 0x000009c0      0 DBM    command db_execute CHECK DATA  
2004-11-30 11:17:37 0x0000079c      0 DBM    command db_execute CHECK TABLE
```

The screenshot shows a Windows Notepad window titled "dbm.prt - Notepad". It contains log entries from a database system. Two specific lines are highlighted with yellow arrows:

```
2008-09-17 10:10:41 0x00001058 INF      419 DBMSrv  Command 'db_online' has ended with return code 0.  
2008-09-17 10:15:00 0x00001058 INF      1 DBMKnl  Sending an administrative statement to the database  
2008-09-17 10:15:00 0x00001058 INF      8 DBMKnl  Statement: CHECK DATA  
2008-09-17 10:15:00 0x00001058 INF      3 DBMKnl  Received the result of an administrative statement from the database  
2008-09-17 10:15:00 0x00001058 INF      9 DBMKnl  Statement: CHECK DATA  
2008-09-17 10:15:00 0x00001058 INF      10 DBMKnl  Returncode: 0
```

### ■ KnIMsg

The screenshot shows a Windows Notepad window titled "KnIMsg.prt - Notepad". It contains a log of database operations. A yellow arrow points to the line where the check operation is completed successfully:

```
2008-09-17 10:15:00 RTE      10815: T27 Calling Kernel_Main  
2008-09-17 10:15:00 CONNECT  19633: Connect req. (DB7705, T27, connection obj. 0x7FF81C18, Node:'BERI'  
2008-09-17 10:15:00 Data     82: Start check database

2008-09-17 10:15:00 Data     79: Check database finished successfully  
2008-09-17 10:15:00 CONNECT  19651: Connection released (DB7705, T27, connection obj. 7FF81C18)  
2008-09-17 10:15:00 RTE      10815: T27 Kernel_Main returned  
2008-09-17 10:21:45 Savepoint 1: Savepoint (time) started by T1
```

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 67

The successful end of CHECK DATA can be checked in **dbm.prt** or in file **KnIMsg (knldiag)**.

If in **dbm.prt** a returncode 0 is delivered the CHECK DATA was successful. In the **KnIMsg** at the end of the progress report a success message is written.

## Consistency Checks (5) – Error Situation

The screenshot shows three windows related to error diagnosis:

- KnIImg.prt - Notepad**: A text file containing log entries from a database check. A red arrow points to a specific line: "11:30:07 Data 47: Check data on database object failed,KNL\_BASE\_ERROR=index\_not\_accessible,ROOT=74502".
- Problem Occurred**: A dialog box showing an error message: "**<Local>:DB7705** Checking database structure (Time of error: 17. September 2008 11:17:40 MESZ)  
Reason:  
SQL error  
-9407,0000000001000000001  
100,Check database finished unsuccessfully  
4,Found not accessible index".
- dbm.prt**: A text file showing administrative statements and their results. It includes:
  - "Ending an administrative statement to the database"
  - "Received the result of an administrative statement from the database"
  - "Statement: CHECK DATA"
  - "Returncode: -9407"
  - "Errorcode: 0x000001058 ERR"
  - "Errorcode: 0x000001058 ERR"
  - "Statement: CHECK DATA"
  - "Returncode: 000000002000000002"
  - "Errorcode: 0x000001058 ERR"

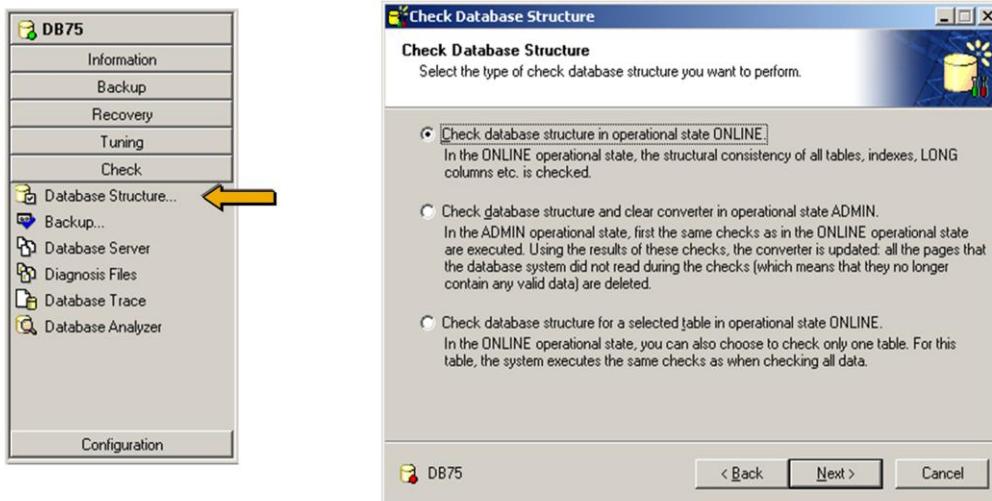

If in **dbm.prt** a returncode unequal to 0 is logged, there is an error situation and the defective data object has to be found out. The roots of the defective B\* trees are listed in **KnIImg**.

At the end of CHECK DATA Database Studio opens a popup showing the first error that occurred. Information about further errors has to be gathered from the diagnosis files.

# Consistency Checks – DBMGUI (1)

- DBMGUI: Check -> Database Structure

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 69

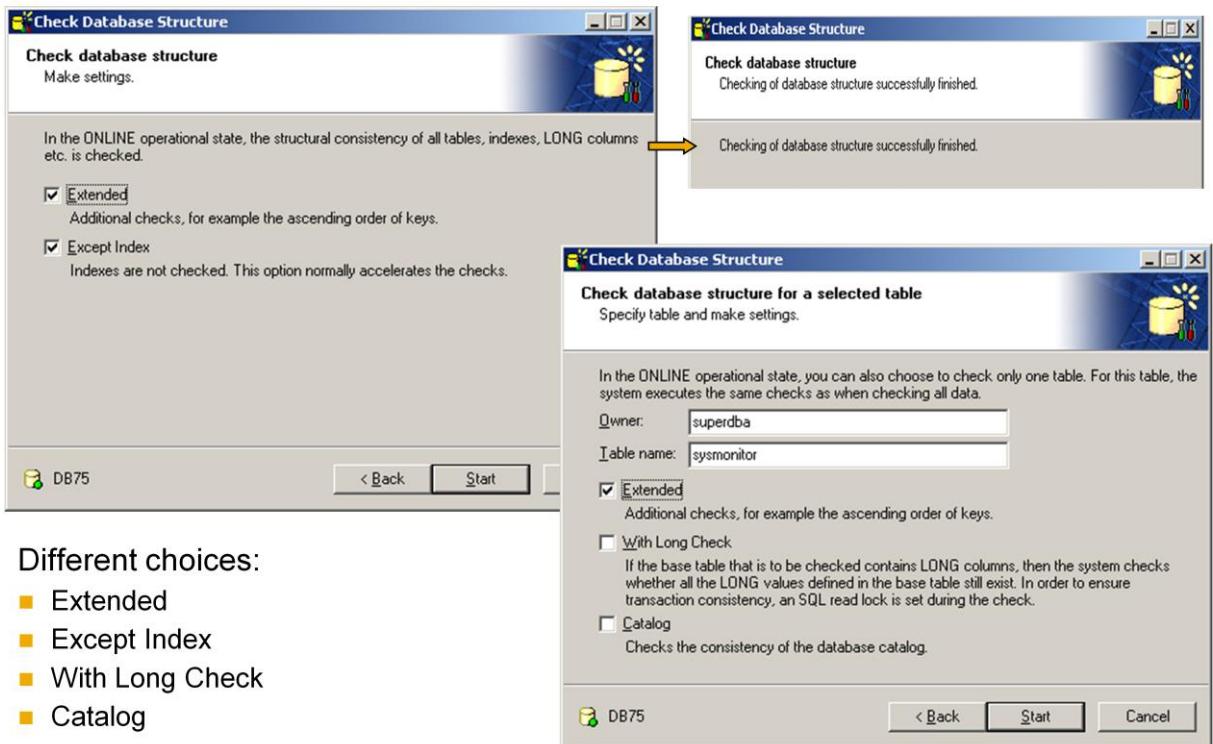

In the DBMGUI, choose **Check -> Database Structure**. There are several options.

A consistency check can be done in various operational states. In the ONLINE operational state, the structural consistency of all tables, indexes, and LOB columns is checked. In the ADMIN operational state, the converter is also updated; pages that are no longer referenced are deleted.

The check can be restricted to a single table.

## Consistency Checks - DBMGUI (2)

SAP

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 70

The selection options EXTENDED, EXCEPT INDEX, WITH LONG CHECK have already been explained.

**CHECK CATALOG** enables you to check the catalog information of a selected table.

## Check Backup (1)

Backups are checked using a service database.

- No data is written to the disks.
- Service database merely occupies disk space.
- Check of parallel backups is possible.
- DBM command: recover\_check

Check if the backup

- is complete
- has valid contents

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 71

Before you overwrite the backups of one generation, you should make sure that you have an intact backup.

Since the check of a backup is executed on a special service database which merely uses disk space for log files, no resource bottleneck occurs.

The service database is automatically registered when a database instance is created and is stored under the name .M<version> (e.g.: .M750019).

(In older releases, the Name \_SAPDB<SID> was used, though the name was shortened to 8 characters, so part of <SID> was lost.)

For a restore, the processes are logged in ***KnIMsg (knldiag)*** and the I/O can be monitored with x\_cons.

## Check Backup (2)

The screenshot shows the SAP MaxDB Database Studio interface. On the left, the 'Servers' tree view includes nodes for Local, Id1032, Idclu2, and Iddbatc. The main window displays a 'Backup History' table with two entries:

Label	Backup Type	Action	Start	Result	Medium
LOG_000000001	LOG	SAVE WARM	17.09.2008 13:17:11	OK	DB7705.log
DAT_000000001	COMPLETE DATA	SAVE WARM	17.09.2008 13:03:56	OK	DB7705.dat

A context menu is open over the second row, with the option 'Check Backup' highlighted. A yellow arrow points from the text 'Right Click: Check Backup' to this menu item. To the right of the main window, a 'Start Backup Check' dialog box is displayed, containing the following information:

You have completed the steps required to perform a backup check. Make the specified medium available and choose 'Start'.

Label: DAT\_000000001 Medium: DB7705.dat Device/File: c:\backup\DB7705.dat

Buttons: Start (highlighted with a yellow arrow) and Cancel.

OR: Check Backup in the context menu of the database

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 72

In the Database Studio, you can execute a check of a backup by choosing '**Check Backup**'.

Then you have to select the appropriate backup medium.

## Check Backup (3)

The screenshot shows two windows related to a database backup check:

**Main Window (Left):** Title: "Check Backup of Database <Local>:DB7705". It displays progress bars for Data (7,48%), Log (0,03%), and Sessions (20,00%). Below the progress bars are tabs: Summary, Backup History, Data Carriers, and Results. The Data Carriers tab is selected, showing a table with columns: Label, Medium, Device/File. It lists two entries: DAT\_000000001 (DB7705.dat) and LOG\_000000001 (DB7705.log). Both entries have green checkmarks. A message at the bottom says: "To continue the check backup make the specified modifications." Below the table are "Continue" and "Cancel" buttons, with a yellow arrow pointing down between them.

**Sub-Window (Right):** Title: "Check Backup of Database <Local>:DB7705". It displays the message "Backup Check Successfully Completed". Below this is another table with columns: Label, Date, Result, Transferred, Left, Medium, Device/File, Size, and N. It contains two rows:

Label	Date	Result	Transferred	Left	Medium	Device/File	Size	N
DAT_000000001	17.09.2008 13:27:49	OK	2.368 KB	0 KB	DB7705.dat	c:\backup\DB7705.dat	278	37
RESTART	17.09.2008 13:32:24	OK						

A message at the bottom of the sub-window says: "The backup check was successfully completed." There is a "Close" button at the bottom right of the sub-window.

A successful execution of a **Check Backup** is marked with a green check mark. After the check of a data backup you will automatically be guided to the check of the corresponding log backups.

## Examples of Problem Situations

- Connect problems
- Log full
- DB full
- Crash, Emergency Shutdown
- System hanger
- Restart problem
- Backup-/Restore problems
- System copy
- I/O problems
- System errors –9026, -9028

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 75

"Connect" problems can usually be reproduced quite easily with R/3trans. Call R3trans with option `-d` or `-X`.

The Precompiler Runtime of the database creates a trace if the variable `SQLOPT` contains the value `"-X"`. The trace is written to the file `SAPDB.<PID of the client process>.pct`.

In this example either the user name or the password is incorrect. The user `SAPXX` is probably not correct.

Check the xuser specifications with the command "`xuser list`". Maintain the xuser data as described in note 39439.

With "Connect" problems, it is often helpful to have a look in the dev logs (the `dev_w*` files from the work directory in the SAP system).

For a few years the WebAS kernel uses the MaxDB client SQLDBC instead of the precompiler. To analyse the cause of connect problems here, too, the call of R3trans -d/-x is the adequate way to find out what's wrong.

If a connect request cannot be executed correctly in most cases errors in the xuser data are responsible for the problems.

R3trans -d creates a file trans.log providing more information about the cause of the problem.

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 77

A Log Full situation first manifests itself in that an hourglass is displayed for all dialog users who are performing change actions. This suggests that the database is at a standstill and the user tasks have been suspended.

The Database Studio directly shows the state of the database next to the database name and additionally provides information about how to handle the error situation in the graphical representation of filling grades.

A quick glance in the DBMGUI shows that the log is 100% full, both in a bar and in text form.

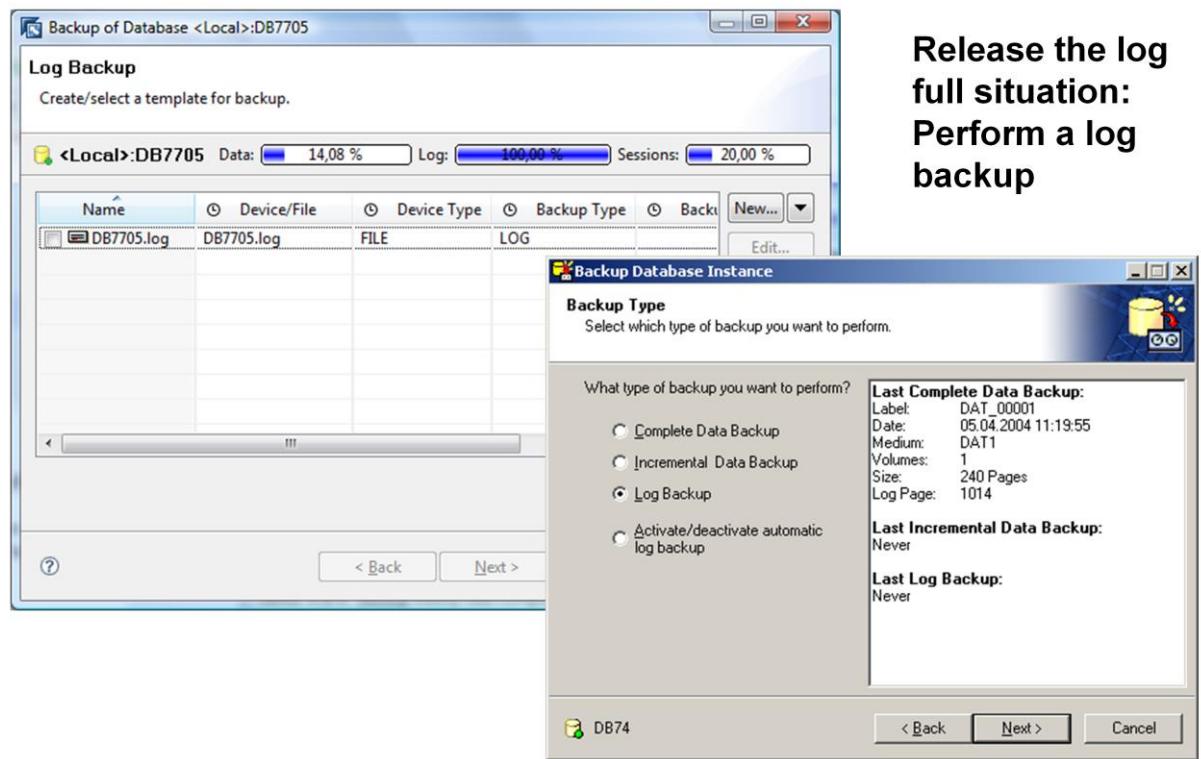

Alternatively, **KnIMsg/knldiag** and **x\_cons** offer the same information.

As a general rule, we recommend using automatic log backup, which usually keeps this situation from happening.

## Log Full - Solution

Release the log full situation:  
Perform a log backup

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 78

A Log Full situation can **ONLY** be resolved by executing a log backup.

The Backup Wizard guides you through the required steps.

Adding a new log volume is NOT a possible way of solving the problem. As log volumes are cyclically overwritten, the pointer is usually 'somewhere in the middle' of the device and cannot jump to a new volume.

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 79

A DB Full situation first manifests itself to the user exactly as it does with a Log Full. The user tasks are suspended and no further actions are possible.

Here too, the DBMGUI (without picture), **KnIMsg/knldiag** and x\_cons provide information about the hang situation.

# DB Full - Solution

SAP

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 80

To resolve a DB Full situation, you have to add another data volume.

To do this with DBMGUI, choose **Configuration -> Volumes'**.

The DBMGUI generates default values for the new volume and directs the rest of the process.

Choose **Administration -> Data Area -> New** in Database Studio to create a new volume.

This problem can be prevented by using the AUTOEXTEND functionality. If a defined filling grade is reached automatically a new volume is added.

## Crash of the Database: kill

knldiag

Signal 9: A thread of the database has been killed with „kill –9“.

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 81

The first place to look after a database crash is ***KnIMsg/knldiag***. In this example, the database process on Unix/Linux received signal 9. Signal 9 comes from "outside" and is not caused by the database. On Unix you can find a short description of the signals in the file `/usr/include/sys/signal.h`. Linux stores these definitions in `/usr/include/bits/signum.h`.

Interesting signals:

- SIGILL                  4                  /\* Illegal instruction (ANSI). \*/  
This signal comes from outside and implies a hardware problem.
- SIGABRT                6                  /\* Abort (ANSI). \*/  
Termination without further information.
- SIGKILL                9                  /\* Kill, unblockable (POSIX). \*/  
Process/thread was terminated with kill.
- SIGBUS                 10                /\* bus error \*/  
Error predominantly in the bus system; usually an error in the database software.
- SIGSEGV                11                /\* Segmentation violation (ANSI). \*/  
Memory overwrite; usually an error in the database software.

## Signal 9 (Resource Problem)

KnlMsgArchive window content:

```

Feb 1 04:57:12 vsa6924 kernel: [1332567.831528] Killed process 7886 (kernel)
[...]
```

Annotations:

- A red arrow points from the KnlMsgArchive window to the line "Kernel exited due to signal 9 [SIGKILL]" in the log.
- A red arrow points from the line "Killed process 7886 (kernel)" in the log back up to the KnlMsgArchive window.
- The text "call of oom-killer" is positioned above the log entry in the KnlMsgArchive window.
- The text "kernel process was killed" is positioned below the log entry in the var\_log\_messages.txt window.

On some operating systems tools make sure to provide resources in situations with not enough memory for all running applications by killing some processes which are using a large amount of memory.

Under Linux, f.e. this is the so-called oom-killer (out of memory).

In the **KnlMsg** you will also find a crash with signal 9. For verification that an operating system tool caused the crash you have to look into the file /var/log/messages. You will find an entry at the same time that a process intentionally was killed because of lack of resources.

To prevent those crashes make sure to enhance the memory or reduce the number of running processes. If you switch off the mechanism you might prevent the „kill“ but the real problem of overcharging the machine still persists.

## Analysis with Post Mortem Console

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 83

To provide more analysis information after a crash situation the so-called post mortem console has been introduced. It can only be used on UNIX systems.

When a database is started, in the sub-directory of the rundirectory rtedump\_dir the files RTEMemory\_Chunk.\* are created containing relevant information from the shared memory for the runtime environment. This information is also accessed when you call x\_cons in running operation.

To allow x\_cons commands also after crash situations these files are maintained for later analysis. If the database is restarted the current RTEMemory\_Chunk.\* are copied to RTEMemory\_Chunk.\*.old. Furthermore in case of a crash they are kept in the diagnose history. With the use of option –p <archive\_path> x\_cons can be informed from which directory the files have to be used.

In the present example the database Q1K crashed. As first analysis step you should search for modules from the backtrace in known problem messages. If it is not a known crash which had happened before and was already analysed the information delivered by the post mortem console might be helpful. x\_cons can be called and look for the formerly active tasks. Via the application PID the command responsible for the crash can be identified in the dev traces.

# Emergency Shutdown: Log I/O Error

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 84

Errors while writing to the database log are very critical, in particular if the database is not being mirrored.

Determine the cause of the I/O error. For this example, the error has been simulated.

If the log is mirrored on the database side, then

- provide a new disk for the log volume,
- transfer the database to the ADMIN operational state and execute a restore for the volume using:  
dbmcli > db\_execute restore log volume '<name of the volume>' ,
- start the database ONLINE.

If the log is mirrored in the system, check whether the error can be corrected in the system. If that is the case, start the database in the ONLINE operational state after the correction has been made.

If the log is irreparable, proceed as follows:

- Create a data backup. The backup is consistent on the basis of the last savepoint.
- Back up the current log area. If the log area cannot be backed up, you can use the generated data backup.
- Initialize the instance when a functional disk has been provided for the log volume. Import the data backup and the generated log backup.  
You use Database Studio (**Initialize Database** or **Create Database**) or the Installation Wizard of the DBMGUI to initialize it.

# Identification of a System Hanger

SAP

A lot of updates on table ZZTELE occupy the dialog processes

Active tasks have the status Vwait (SQL lock)

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 85

The screenshot shows the SAP Process Overview (Prozessübersicht) interface. A callout box highlights a process (row 7) with PID 1416, which is executing an update on the ZZTELE table. Another callout box points to a database console window showing active tasks with the status 'Vwait' (SQL lock). The tasks listed are T37, T39, T40, T60, and T65.

ID	UKT	UNIX	TASK	APPL	Current	Timeout	Region	Wait item
			tid	pid	state	priority	cnt	try
T37	6	1232	User	1411	Vwait	0	0	34 0(s)
T39	6	1234	User	1413	Vwait	0	0	20 0(s)
T40	6	1235	User	1410	Vwait	0	0	37 0(s)
T60	7	1255	User	15449	Vwait	0	0	27 0(s)
T65	7	1260	User	1412	Vwait	0	0	36 0(s)

This example shows a system hanger situation.

Transaction sm50 or sm66 show numerous dialog processes that are executing updates on table ZZTELE. If transactions sm50 and sm66 are no longer usable because all dialog processes are occupied, call the program **dpmon** on the operating system level. In the 'Menu' there you'll see a comparable output.

The database console shows the respective tasks in the Vwait status. The tasks are waiting for the release of an SQL lock.

At present no other task is active in the database; that is, the lock holder is active in the application or waiting for user input.

# System Hanger: Who is the Lock Holder?

SAP

The screenshot shows the SAP System Monitor interface. The title bar reads "Exklusive SQL-Wartesituationen". The left sidebar has a tree view with nodes like E30, Eigenschaften, Alert-Monitor, Aktueller Status, Kernel-Thr, Task-M, Thread, I/O-Operati, Kritische A, SQL-Sperr, Wartes, Übersi, Speicherbe, Systemein, and Werkzeuge. The main area is titled "Exklusive Wartesituationen" and contains a table with the following data:

Task-ID	Appl.-ID	Appl.-Server	Spe...	Sperrart	Tabellenname	Task-ID	Appl.-ID	Appl.-Server	Warte
48	9008	dewdfm189.wdf.sap.corp		row_exclusive	ZZTELE	40	1410	p34777	
48	9008	dewdfm189.wdf.sap.corp		row_exclusive	ZZTELE	65	1412	p34777	
48	9008	dewdfm189.wdf.sap.corp		row_exclusive	ZZTELE	37	1411	p34777	
48	9008	dewdfm189.wdf.sap.corp		row_exclusive	ZZTELE	60	15449	p34777	
48	9008	dewdfm189.wdf.sap.corp		row_exclusive	ZZTELE	39	1413	p34777	

A callout bubble points to the first row of the table with the text: "Task 48 keeps the lock and belongs to application process 9008. It is not known as work process."

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 86

Transaction db50 provides more information under 'SQL Locks -> Wait Situations'. All waiting tasks are waiting for task 48. This task belongs to application process 9008 on the server dewdfm189. The server is not a SAP application server.

User operations generally have priority. Task 48 should therefore be forced to release the lock.

# System Hanger: What is Task 48 doing?

SAP

The screenshot shows the SAP Task Manager interface. The left sidebar lists various system components like E30, Alert-Monitor, and Kernel-Thr. The main area displays a table of tasks. A red arrow points from the text below to the 'Kommando abbrechen' (Cancel Command) button in the toolbar above the table. Another red arrow points from the text below to the table itself.

ID	Thread-ID	Task-Typ	A.	Task-Zustand	Zustandsbeschreibung	Wart...	Warten ...	Applikation...	A
37	1230	User		Vwait		48		1411	p
39	1230	User		Vwait		48		1413	p
40	1230	User		Vwait		48		1410	p
60	1255	User		Vwait		48		15449	p
64	1255	User		Running				1414	p
65	1255	User		Vwait		48		1412	p

**Task 48 is not active in the database.  
Task 64 works for transaction db50.**

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 87

Under '**Current Status -> Kernel Threads -> Task Manager**', transaction db50 displays the task activities. Task 48 is not active. The running task 64 formats the information for db50 itself.

To terminate 48, display all user tasks. Select task 48 and choose 'End Session'.

It is not possible to terminate a command for task 48 if task 48 is not active. The lock can only be released by terminating the transaction. If the locking transaction is not active in the database, its transaction can be terminated by closing the session.

If a work process which is holding locks is active on the database, the termination of the command leads to the termination of the transaction. When it receives return code -102, the SAP system rolls back the transaction and writes a short dump.

## Standstill of the System: Eliminate Cause

```

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 88

The action '**Terminate Command**' in transaction db50 corresponds to the console command 'cancel <task>'. You terminate user sessions with 'kill <task>'.

Terminating the locking transaction can take some time. MaxDB works with cooperative multitasking. The tasks are not managed through a dispatcher instance. Some actions only check whether the termination flag is set every 30 seconds.

In the console output, if the termination flag was set, this is indicated by an exclamation mark. If the task remains active (in particular in the Running and I/OWait statuses), it executes a rollback of the changes that have already been made.

## Restart Failed: Lack of Memory

The screenshot shows two windows from the SAP Diagnosis Files interface. The top window, titled 'Check - Diagnosis Files - Database Messages', displays a log of system messages. Red arrows point to several error messages indicating memory limits being reached or exceeded. The bottom window, titled 'd025448 on p:/sapmnt/home1/d025448', shows a detailed log of environment variables and their values. A red arrow points to a specific entry for 'stack memory size'. A yellow arrow labeled 'xserver\*.prt' points to the bottom window, indicating where to check process limitations.

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis (diag)

In this example the database cannot transfer to the ADMIN operational state because the operating system cannot allocate enough memory.

The file **knldiag** shows an excerpt of the limitations for the user. These limitations are inherited from the owner of the x\_server process.

When you start the x\_server, make sure that the user has set sufficient limitations. On Unix/Linux, you set limitations either with limit or ulimit, depending on the shell.

Check the limitations of the x\_server process in the file <indepdatopath>/wrk/xserver\*.prt.

This case can be resolved by setting the limitations correctly and restarting the x\_server.

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 90

The file **dbm.knl** presents a first overview of which backups and which restore activities were successfully executed; or for a more orderly display in the form of a backup history in the Database Studio choose **Administration -> Backup** or **Information->Backup History** in the DBMGUI.

If any errors have occurred, the causes are noted in brief. More precise information can be found in **KnIMsg/knldiag**.

Up to version 7.6 the file **dbm.utl** provides information about backups. As of version 7.7 the information from **dbm.utl** is integrated into other diagnosis files (**KnIMsg/dbm.prt**).

If external backup tools (Networker, ADSM, Omnipack, etc.) and the backint interface are being used, you should also check their logs, which are described in the following.

## Example: Backup / Restore (1)

```
The restore from the system <SID> with backup from 15.01.01 was
killed with:
2004-01-16 20:25:53      13 ERR 54001 I/O      page 00C29008010D0200...008
2004-01-16 20:25:53      13 ERR 52015 RESTORE  write/check count mismatch
2004-01-16 20:25:53      12 ERR 52012 RESTORE  error occured, basis_err 30
2004-01-16 20:25:53      12 ERR 51080 SYSERROR -9026 Message not available
The restore with the backup from 16.01 was killed with:
2004-01-16 17:11:31      13 ERR 54001 I/O      page 00AA5684010D0200...203
2004-01-16 17:11:31      13 ERR 52015 RESTORE  write/check count mismatch
2004-01-16 17:11:31      12 ERR 52012 RESTORE  error occured, basis_err 30
2004-01-16 17:11:31      12 ERR 51080 SYSERROR -9026 Message not available
```

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 91

In the present example, the restoring of a backup terminated with a system error.

First, the system attempts to repeat the procedure with various backups. It turns out that several backups have already been affected and that a restore returns error -9026.

At this stage, the user should check the logs to see what they say about the backups, e.g. whether they were successful, etc.

## Example: Backup / Restore (2)

```
UTLPRT:  
=====  
2004-01-19 01:00:11 400B1E0B0006 0000 SDB SAVE DATA QUICK TO '/nsr/sap  
2004-01-19 03:48:08 400B1E0B0006 0001 RET RETURNCODE 0 ←  
[...]  
  
DBMPRT:  
=====  
2004-01-19 01:00:11 0x00007227 0 DBM  
  command backup_start nsr_full RECOVERY DATA AUTOIGNORE  
2004-01-19 03:49:45 0x00007227 ERR -24920 DBM  
  ERR_BACKUPPOP: backup operation was unsuccessful  
  0x00007227 ERR -24920 DBM  
The backup tool failed with 0 as sum of exit codes.
```

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 92

Looking at **dbm.utl** is not sufficient! The return code 0 here shows only that the backup was successful from the database's point of view. In other words, it correctly delivered all database pages to the pipe of the external database tool.

In **dbm.prt** we see that the backup could not be completed successfully. The cause is not immediately visible in this file, but the tool has signaled that the backup failed from its point of view.

Backups that have the return code 0 in **dbm.utl** (that is, on the kernel side) but failed according to **dbm.prt** are identified as having failed in the backup history (DBMCLI -> backup\_history\_list as well as in DBMGUI). The error code, then, is the error code of the backup/restore (generally -24920).

## Example: Backup / Restore (3)

```
BACKEBL:  
=====  
  
2004-01-19 03:49:44  
Analyzing output of NetWorker.  
    Have found a completion message in the NetWorker output file  
    '/var/tmp/temp1074470411-1' in line:  
    save: S6F level=full, 130 GB 02:43:44      5 files  
    Have found a savetime message in the NetWorker output file  
    '/var/tmp/temp1074470411-1' in line:  
    completed savetime=1074470655  
    NetWorker has saved only 140123308032 bytes ←  
    (the database kernel has saved 159754027008 bytes).  
The backup size of database and NetWorker are different.  
  
2004-01-19 03:49:44  
Filling reply buffer.  
    Have encountered error -24920:  
        The backup tool failed with 0 as sum of exit codes.  
  
    Constructed the following reply:  
        ERR  
        -24920,ERR_BACKUPPOP: backup operation was unsuccessful  
        The backup tool failed with 0 as sum of exit codes.  
Reply buffer filled.
```

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 93

The log of the backup tool provides information as to why the backup was not considered successful.

There is a big discrepancy between the number of bytes backed up by the database kernel and the number of bytes given by the Networker which cannot be explained by rounding errors.

Here we cannot identify the cause, which could only be determined in cooperation with the Networker manufacturer Legato. While a file system backup was in progress, the Networker failed to end the data backup correctly when it accessed the data backup pipe.

MaxDB now ensures that file system and database backups remain separate.

## Example: Faulty Tape Devices

### 1st attempt: RESTORE DATA was successful

#### RESTORE LOG fails

The recovery of the system <SID> breaks with  
2004-01-16 20:11:11 13 ERR 52015 RESTORE bad log page 98897294  
2004-01-16 20:11:25 13 ERR 52608 RESTART LOCAL: failed  
2004-01-16 20:11:29 12 ERR 52012 RESTORE error occurred, basis\_err 90  
2004-01-16 20:11:29 12 ERR 51080 SYSERROR -9030 Message not available

### 2nd attempt: RESTORE DATA fails, but is later successful with the identical backup

Excerpt from the Backup History:

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 94

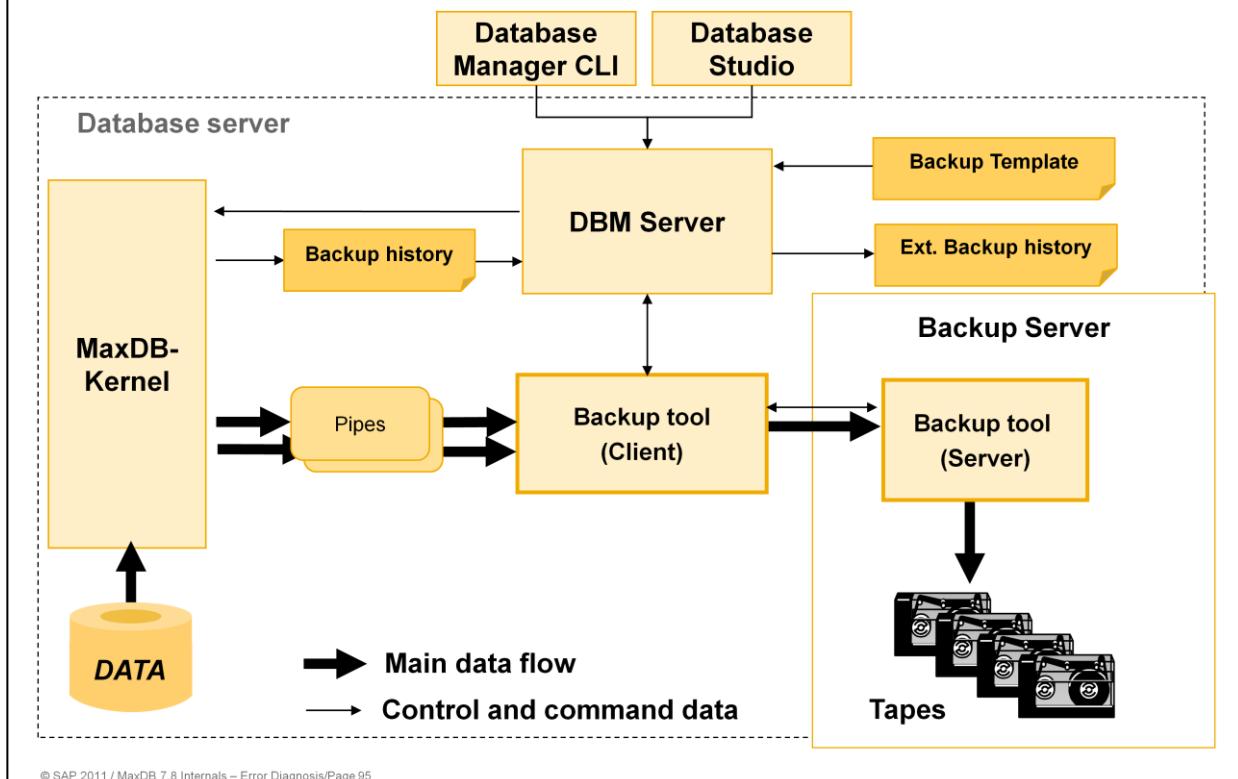

In this example, the restore of a log backup terminates with system error -9030 (bad log page).

During the attempt to repeat the restore process completely, there was already a problem with the data backup. Subsequently, however, the data backup (with the same label) was successfully recovered.

This non-deterministic behavior suggests a problem with the tape peripherals. In such cases, checking the tape drives and the controller and changing the defective device will solve the problem.

With luck, the problem will have been merely a read error; in the worst case scenario, the tapes will already have been incorrectly filled.

# Data and Log Backups Using External Tools

Backups for SAP MaxDB are always triggered by the DBM Server – either through the DBMCLI or through Database Studio. The DBM Server is also the component which starts the external backup tool. The backup procedure works as follows:

1. The DBM Server sends the backup command to the database kernel.
2. The database kernel creates and opens one or more pipes (as specified in the backup template used by the DBM Server).
3. The DBM Server starts the backup client of the backup tool as soon as the database kernel opens the first pipe. Which backup tool is to be used is also specified in the backup template.
4. The backup tool opens the pipes, transfers the data to the backup server, and stores it on tape.
5. The database kernel records the result of the backup in the backup history.
6. The DBM server requests the unique backup IDs (External Backup ID) from the backup tool and enters these in the External Backup History (dbm.ebf). -This makes it possible to link the backup IDs generated by the database kernel with the backup ID of the external backup tool.
7. The backup is logged in the External Backup Protocol (dbm.ebp).

External backup tools can not be used directly for automatic log backups. Automatic log backups are triggered directly by the database kernel, which isn't aware of the configuration of external backup tools. Automatic log backups can only be performed to versioned files. However, the usage of a so called log staging area is supported which can be configured in a way that the versioned files created by the database kernel are backed up to an external backup tool. Details about this follow later in the session.

# External Backup Tools

The screenshot shows the SAP Database Studio interface for managing backup templates. At the top, there is a table titled "Templates" showing a list of existing backup templates:

Name	Device/File	Device Type	Backup Type	Backup Tool	Size	Overwrite
Complete data	C:\sdb\Backups\d...	FILE	COMPLETE DATA			YES
Complete data Compressed	C:\sdb\Backups\d...	FILE	COMPLETE DATA			
DataBackupBackint	\.\pipe\EXPERTD...	PIPE	COMPLETE DATA	BACKINT		
DataBackupBackintParallel	\.\pipe\EXPERTD...	PIPE	COMPLETE DATA	BACKINT		
INITIALBACKUP	C:\sdb\data\EXPE...	FILE	COMPLETE DATA			

Below the table are two dialog boxes showing detailed configuration for specific backup templates:

- Backup Template for Id8198:N025588:** This template is for a single backup to a file named "ndata". It uses COMPLETE DATA type, PIPE device, and NETWORKER backup tool. The device/file path is "\backup\ndata".
- Backup Template for bern00176467A:EXPERTDB:** This template is for a parallel backup. It contains two entries: "Device 1" (PIPE, EXPERTDB\_0) and "Device 2" (PIPE, EXPERTDB\_0). Both use COMPLETE DATA type, PIPE device, and BACKINT backup tool.

At the bottom left of the interface, there is a copyright notice: © SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 96

Before you can perform backups, you must define the relevant backup templates. You can create and change backup templates or template groups of parallel backup media in Database Studio in the backup section of the Administration window by choosing Templates.

To be able to create a parallel backup template, you must set the value of the "MaxBackupMedia" parameter to match the number of individual templates in a parallel backup template. For example, if a template group is to comprise 10 individual templates, the value of the "MaxBackupMedia" parameter must be "10" (or higher).

You can specify the following information for the template:

- **Name** of the backup template. This name is freely definable and is not dependent on the storage location used (Device/File).
- **Backup Type**: Specify the type of backup for which this template is to be used.
- **Device Type**: Tape, file, or pipe – if an external backup tool is to be used, the Device Type must be set to pipe.
- **Backup Tool**: Type of external backup tool (if applicable)
- **Device/File**: Path to a device, name of a defined pipe, or name of a file including its path. If you do not specify a path, a file is created in the run directory of the database instance.
- **Size**: Maximum size of the backups that can be created on this template (if you do not make an entry in this field, files of unlimited size can be created).
- **OS Command**: In this field, you can specify operating system commands for backups to tape.
- **Overwrite**: This option enables you to perform successive backups to the same file, overwriting the previous backup each time. Use this function carefully since it makes it impossible to restore one of the previous backups.
- **Block Size**: The entry in this field defines the size of the data blocks to be written to the template. If page clustering is used for the instance, the value in this field must be larger than a multiple of the cluster size used (minimum block size, for example, of "64").
- **Autoloader**: Select the Autoloader checkbox if you want to use a tape device with automatic tape swapping.

The above examples show one template which can be used for a backup to Networker and a template group comprising of 2 single templates which can be used for a parallel backup with Backint.

## Supported External Backup Tools

- Networker (NSR)
- Tivoli Storage Manager (TSM)
- Tools supporting the interfaces *Backint for MaxDB* or *Backint for Oracle* (BACK)

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 97

MaxDB supports different external backup tools and backup techniques:

- Networker (NSR)
- Tivoli Storage Manager (TSM)
- Tools supporting the interfaces *Backint for MaxDB* or *Backint for Oracle* (BACK) f.e.
  - HP Data Protector >6.0 supports *Backint for MaxDB*
  - Comvault QiNetix > 6.1 supports *Backint for MaxDB*
  - All other external backup tools known to the market which are not mentioned here have to be configured via *Backint for Oracle*. According to experience they need additional adapters from the vendors of external backup tools.

To support one of these tools it is necessary to define pipe as *Device Type* of the backup template.

Some more example definitions for templates under Unix and Windows:

- Windows:    First tape device: \\.\tape0  
              Pipe: \\.\pipe\PipeName
- UNIX:      Tape device, f.e.: /dev/tape0  
              Pipes: /backup/pipe0

Template definitions are stored in the file **dbm.mmm** in the rundirectory of the database instance.

► Templates

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 98

The Backup History contains information about all successful and unsuccessful backups. Detailed information for each entry is available in the Details section. Here also the external backup ID is displayed, if an external backup tool was used.

- `backup_start <template_name> DATA|PAGES|LOG`

**Example:**

```
backup_start "DataBackupBackint" DATA
```

- `backup_ext_ids_get`

**Example:**

```
backup_ext_ids_get DataBackupBackint
```

- `backup_ext_ids_list`

**Example output:**

```
END
AVAILABLE|EXPERTDB EXPERTDB+12 \\.\pipe\EXPERTDB_0|DATA MIGRATION|2010-09-29 10:11:40|
AVAILABLE|EXPERTDB EXPERTDB+13 \\.\pipe\EXPERTDB_1|DATA MIGRATION|2010-09-29 10:11:40|
AVAILABLE|EXPERTDB EXPERTDB+18 \\.\pipe\EXPERTDBpipe|DATA MIGRATION|2010-09-29 10:47:58|
```

- `recover_start <template_name> <backup_type> [ExternalBackupID <ebid_list>] [<nnn>]`

**Example:**

```
recover_start "DataBackupBackint" DATA EBID "EXPERTDB
EXPERTDB+18 \\.\pipe\EXPERTDBpipe"
```

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 99

When using DBMCLI, a backup of the database is done with the help of the `backup_start` command.

As the DBMServer recognizes the backup tool to be used from the backup template, there is no difference in the `backup` command between a backup with and a backup without a backup tool.

As more than one DBMServer command is needed for displaying the External Backup Identifiers, an interactive dbmcli session must be used.

The columns of the displayed list are separated by the pipe character (|).

The list has the following format:

`<Availability>|<External Backup ID>|<backup type>|<date_time>`

If in an answer to `backup_ext_ids_list` or `backup_ext_ids_listnext` a line with a keyword `CONTINUE` follows the line with the keyword `OK`, the next part of the list can be requested with the `backup_ext_ids_listnext` command.

A restore is done with the commands `recover_start` and `recover_replace` (for restoring more than one log backup).

The keyword `EBID` (or `ExternalBackupID`) is followed by a comma-separated list of External Backup IDs. With parallel backups, all External Backup Identifiers of the individual backup parts must be transmitted as a comma-separated list enclosed in double quotes ("<ExtBackupID\_1>, <ExtBackupID\_2>, ..., <ExtBackupID\_n>").

Further Examples:

```
recover_start ADSM LOG EBID P47579_DB7_2001.03.30_15.51.20_SAVELOG_ADSM
```

```
recover_start NSR DATA EBID "NST 985877420 P47579"
```

```
recover_start BACK PAGES EBID "DB72 985963853 \\.\pipe\b1,DB72 985963913 \\.\pipe\b2"
```

## Relevant Log Files

These log files might be relevant in case a backup or recovery using an external backup tool fails:

- Database Manager log file (**dbm.prt**)
- External Backup Protocol (**dbm.ebp**)
- External Backup Log (**dbm.ebl**)
- External Backup History **dbm.ebf**
- Database Messages (**KnlIMsg**)

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 100

The database manager log file **dbm.prt** contains the backup and recovery calls and – if an error occurred - the error message. Therefore this log file can (in addition to the backup history and the external backup history) be used to check the success of a backup/recovery.

Detailed information regarding the backup/recovery can be found in the external backup protocol (or if this file has already been overwritten in the external backup log **dbm.ebl**). In addition to information about the configuration parameter of the external backup tool, **dbm.ebp** contains information about the commands sent to the database kernel as well as the backup tool call. The error position makes it possible to identify which component was responsible for the problem.

Depending on the cause of the error, it might be necessary to analyze log files of the backup tool.

In case the cause for the backup or recovery failure is not the communication with the external backup tool or problems of the external backup tool, but in the actual processing of the data by the database kernel, the database messages file **KnlIMsg** should be checked for more detailed information regarding the problem.

## Example: Analysis with dbm.prt

### dbm.prt:

```
INF      283 DBMSrv  Command 'backup_start "DataBackupBackint" DATA' is being executed.
INF      1 DBMKnl  Sending an administrative statement to the database

CHECKPOINT MEDIANAME 'DataBackupBackint'
ERR      3 DBMKnl  Received the result of an administrative statement from the database
ERR      9 DBMKnl  Statement:  SAVE DATA QUICK TO '\\.\pipe\EXPERTDBpipe' PIPE BLOCKSIZE 8 NO
CHECKPOINT MEDIANAME 'DataBackupBackint'
ERR      10 DBMKnl  Returncode: -903
ERR      5 DBMKnl  Errortext: Host file I/O error
ERR    -24580 DBMSrv  ERR_COMMAND_FAILED: Command 'backup_start' has ended and failed with return
code -24920.
ERR    -24920 DBMSrv  ERR_BACKUPPOP: backup operation was unsuccessful
ERR    -24778 DBMSrv  The backup tool failed with 2 as sum of exit codes. The database request was
canceled and ended with error -903.
```

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 101

In file **dbm.prt** you can see that the backup was started to a backup template called DataBackupBackint. The exact statement sent to the database kernel is logged as well as an error messages.

Error message „The backup tool failed with 2 as sum of exit codes. The database request was canceled and ended with error -903.“ indicates, that the backup tool caused the problem and that the database request was only cancelled as a result of that failure. So the error analysis has to concentrate on the backup tool and its configuration.

**dbm.prt** is stored in the run directory of the database (default: <indepdatapath>/wrk/<SID>).

Access via DB50: *Properties -> Files -> DBMPRT*

Access via Database Studio: *Diagnosis Files -> Database Manager Log File*

## Example: Analysis with dbm.ebp I

### dbm.ebp:

```
2010-09-29 15:00:03
Checking existence and configuration of Backint for MaxDB.
  Using configuration variable 'BSI_ENV' = 'C:\TOOLS\parfiles\bsi.env' as path of the configuration
file of Backint for MaxDB.
    Setting environment variable 'BSI_ENV' for the path of the configuration file of Backint for MaxDB
to configuration value 'C:\TOOLS\parfiles\bsi.env'.
  Reading the Backint for MaxDB configuration file 'C:\TOOLS\parfiles\bsi.env'.
    Found keyword 'BACKINT' with value 'C:\sdb\expertdb\db\bin\backint.exe'.
    Found keyword 'INPUT' with value 'C:\TOOLS\parfiles\backint4MAXDB.in'.
    Found keyword 'OUTPUT' with value 'C:\TOOLS\parfiles\backint4MAXDB.out'.
    Found keyword 'ERROROUTPUT' with value 'C:\TOOLS\parfiles\backint4MAXDB.err'.
    Found keyword 'PARAMETERFILE' with value 'C:\TOOLS\parfiles\backintmaxdbconfig.par'.
    Found keyword 'TIMEOUT_SUCCESS' with value '600'.
    Found keyword 'TIMEOUT_FAILURE' with value '300'.
Finished reading of the Backint for MaxDB configuration file.
...
2010-09-29 15:00:03
Starting database action for the backup.
  Requesting 'SAVE DATA QUICK TO '\\.\pipe\EXPERTDBpipe' PIPE BLOCKSIZE 8 NO CHECKPOINT MEDIANAME
'DataBackupBackint' from db-kernel.
The database is working on the request.
...
2010-09-29 15:00:04
Starting Backint for MaxDB.
  Starting Backint for MaxDB process 'C:\sdb\expertdb\db\bin\backint.exe -u EXPERTDB -f backup -t
file -p C:\TOOLS\parfiles\backintmaxdbconfig.par -i C:\TOOLS\parfiles\backint4MAXDB.in -c
>>C:\TOOLS\parfiles\backint4MAXDB.out 2>>C:\TOOLS\parfiles\backint4MAXDB.err'.
  Process was started successfully.
Backint for MaxDB has been started successfully.
```

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 102

This is the beginning of file **dbm.ebp**. You can see that variable BSI\_ENV is set to C:\TOOLS\parfiles\bsi.env. Next, the configuration parameters read from this file are listed. In case a parameter is spelled incorrectly, this would be visible here, as unknown keywords are explicitly listed.

In this example, the configuration file is fine.

The backup request was sent to the database successfully and afterwards Backint for MaxDB was started successfully as well.

So far, everything looks fine – however, the log file is continued on the next slide...

## Example: Analysis with dbm.ebp II

```
2010-09-29 15:00:04
Waiting for end of the backup operation.
2010-09-29 15:00:04 The backup tool is running.
2010-09-29 15:00:04 The database is working on the request.
2010-09-29 15:00:05 The backup tool process has finished work with return code 2.
2010-09-29 15:00:09 The database is working on the request.
2010-09-29 15:00:19 The database is working on the request.
2010-09-29 15:00:34 The database is working on the request.
2010-09-29 15:00:54 The database is working on the request.
2010-09-29 15:01:06 Canceling Utility-task after a timeout of 60 seconds elapsed ... OK.
2010-09-29 15:01:07 The database has finished work on the request.

...
2010-09-29 15:01:07
Cleaning up.
Copying output of Backint for MaxDB to this file.
----- Begin of output of Backint for MaxDB (C:\TOOLS\parfiles\backint4MAXDB.out)-----
Reading parameter file C:\TOOLS\parfiles\backintmaxdbconfig.par.

----- End of output of Backint for MaxDB (C:\TOOLS\parfiles\backint4MAXDB.out)-----
Removed Backint for MaxDB's temporary output file 'C:\TOOLS\parfiles\backint4MAXDB.out'.
Copying error output of Backint for MaxDB to this file.
----- Begin of error output of Backint for MaxDB (C:\TOOLS\parfiles\backint4MAXDB.err)-----
The file 'C:\TOOLS\parfiles\backintmaxdbconfig.par' does not exist.
Could not open the parameter file.

----- End of error output of Backint for MaxDB (C:\TOOLS\parfiles\backint4MAXDB.err)-----
Removed Backint for MaxDB's temporary error output file 'C:\TOOLS\parfiles\backint4MAXDB.err'.
Removed the Backint for MaxDB input file 'C:\TOOLS\parfiles\backint4MAXDB.in'.
Have finished clean up successfully.
```

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 103

Once the database kernel and the backup tool are started, the DBMServer determines their state regularly. As you can see, the backup tool failed shortly after it was started, error message „The backup tool process has finished work with return code 2.“ is logged.

As a consequence of that, the database request was cancelled by the DBMServer.

In the output information of Backint for MaxDB you can find the reason for the failure: the parameter file 'C:\TOOLS\parfiles\backintmaxdbconfig.par' specified in the bsi.env file could not be found by Backint for MaxDB. Therefore the tool could not start to work on the backup request.

## External Backup History

### External Backup History (dbm.ebf)

- Contains the backup history including the external backup IDs.
- Is written consecutively, not cyclically overwritten.

#### Example output:

```
4CA1B98A0013|DAT_000000026||DATA MIGRATION|2010-09-28 11:46:51|BACK|-24920|The backup tool failed with 2 as sum

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 104

The file **dbm.ebf** contains the backup history, the backup ID, external backup IDs and error messages. This file is written consecutively and is NOT cyclically overwritten, so that the entire backup history is available for support.

If a backup tool was able to backup successfully, but could not determine the external backup ID, the backup is entered as failed in the backup history.

**dbm.ebf** is stored in the run directory of the database (default: <indepdatapath>/wrk/<SID>).

Access via DB50: *Properties -> Files -> BACKEBF*

Access via Database Studio: *Diagnosis Files -> External Backup History*

# Error during System Copy

The screenshot shows three windows related to database creation:

- DBM74 - Initialize Database Instance**: A dialog box for "Create and start instance". It shows fields for "User Name" (superdba), "Password", and "Confirm Password". A note says: "If you want to restore the database instance, the Installation Wizard will start the Recovery Wizard after creating the database instance. The Database Manager System Administrator will be restored from the backup."
- dbm.prt**: A text file showing database creation commands. Yellow arrows point to the "db\_activate" command and the "recover\_start data" command.
- knldiag - Notepad**: A text file showing kernel logs. Red boxes highlight two error messages:
  - "Initialization of log for 'restart' failed with 'LogAndDataIncompatible'"
  - "DBIdentifier of dataVolume (P124984.wdf.sap.corp:HOTELDB\_20041223\_105938) and LogVolume (P124984.wdf.sap.corp:HOTELDB\_20050127\_152929)"

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 105

One typical user error with system copies is to first completely install a database (including restart and loading the system tables) and only then import a backup. This often leads to confusion when it then turns out that it is no longer an "empty DB".

The user chose '**Create and start instance**' instead of '**Create instance for recovery**' in the DBMGUI.

The individual steps can be viewed in **dbm.prt**. We can see that **db\_activate** was carried out, which represents the first restart of a DB, and that only afterwards a backup was imported.

The system's reaction to this error is somewhat different than in earlier versions (<= 7.3). The system no longer issues return code -8003 „Log and Data must be compatible“ because the database is immediately transferred to the OFFLINE operational state and the DBMGUI no longer receives a message about the exact cause of the error. This ensures that the memory areas can be completely cleared.

**KnIMsg** reports that the cause of the shutdown here again was **LogAndDataIncompatible**, albeit without the familiar return code.

It is also noted that the DBIdentifiers of the data and log volumes do not match.

## I/O Error: Verification of Checksum in Index Page

The screenshot shows the SAP Database Manager interface. At the top, a log window titled 'Check - Diagnosis Files - Database Messages' displays a series of error messages related to checksum verification. A red box highlights several entries where the calculated checksum (618008976) does not match the found checksum (618000000). Below this, the 'Database Manager' window is open, showing the 'Recovery - Indexes' tab selected. On the left, a sidebar menu has 'Index' highlighted. The main pane shows a table of indexes for the database 'p34777:TEST'. One index, 'TEST\_1', is listed with the status 'BAD'. The status bar at the bottom indicates: © SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 106.

After a data page was read from a data volume, checksum 618008976 was calculated. Before writing the block, checksum 618000000 was calculated and written to the block. Apparently the block is not situated correctly on the disk.

This read I/O is repeated twice. If the error occurs every time, the database assumes that the block is defective. This is a block for an index (secondary key tree). The index is marked as BAD.

Check the I/O system. If the damage to the I/O system can be repaired, you can delete the index and then regenerate it.

Under '**Recovery -> Index**', the DBMGUI displays the indexes marked as BAD. You can select the index and recreate it.

Regardless of whether or not you are able to identify errors in the I/O system, it is a good idea to run a **CHECK DATA** in such a case.

# DB50: Recreate Index

The screenshot shows the SAP System Monitor interface. On the left, there's a navigation tree under 'MH\_MYDB' with sections like 'Current Status', 'Problem Analysis', and 'SQL Performance'. In the main area, a table lists database objects. A red arrow points to the 'Bad Indexes' tab. Below the table, a dialog box titled 'Restore Bad Indexes' contains a warning message about the time required for restoration and a question asking if the user wants to proceed.

Table / Index / Column	P...	Sort	Type	C...	A...	U...	Accesses	Reset Date	Time	Creation D...	Time	
MONA.BKPF												
BKPF-1												
· MANDT			1	ASC				0	26.07.2006	09:06:17	26.07.2006	09:06:17
· BUKRS			2	ASC								
· BSTAT			3	ASC								
· XBLNR			4	ASC								
BKPF-2								10	26.07.2006	09:06:17	26.07.2006	09:06:17
· MANDT			1	ASC								
· BUKRS			2	ASC								
· BSTAT			3	ASC								
· BUDAT			4	ASC								
BKPF-3								0	26.07.2006	09:06:17	26.07.2006	09:06:17
· MANDT			1	ASC								
· BUKRS			2	ASC								

Restore Bad Indexes

Restoring indexes can take a long time, depending on the table size.  
While an index is being restored, the associated table cannot be accessed.

Restoring indexes should therefore be performed at a time of minimal workload.  
You should restore indexes of large tables in the background.

Do you want to restore the selected bad index now?

Corrupted indexes (different example) can directly be recreated by using transaction db50. Mark the corrupted index and choose **Restore Index**.

Attention: Up to version 7.7.4 during index creation the corresponding table is locked for write transactions.

## I/O Error: Verification of Checksum in Data Page

SAP

The screenshot shows the SAP MaxDB 7.8 Internal Error Diagnosis interface. At the top, a window titled "Check - Diagnosis Files - Database Messages" displays a log of errors from April 26, 2004, at 10:35:48. The log entries indicate checksum mismatches and bad data pages across various tables and indexes. Below this is "SQL SQL Dialog 1" containing a query to select table and index names, type, and root for the table with root 75569. The result shows one entry for the TEST table. To the right is "SQL SQL Dialog 2" with the command "check table test extended". A message box in Dialog 2 indicates an error: "Auto Commit: On, SQL Mode: Internal, Isolation Level: Not Committed General error: 9026 POS(1) System error: BD Bad datapage". The bottom status bar shows the copyright notice: "© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 108".

In this case, too, a block was read whose checksum did not match with the calculated value. According to the ROOTS view, this tree belongs to the TEST table.

In such a case, check the table with the **CHECK TABLE EXTENDED** statement (default as of 7.6.01). With the option EXTENDED, the sequence of the primary keys is checked on all B\* tree levels.

If CHECK TABLE does not return any errors, the table is intact. Note that in disk mirroring, depending on the disk used for the I/O, a correct block and then an incorrect block may be returned.

If CHECK TABLE continues to return the error, you have the following options:

- Restore the database
- Delete the tables and load the data from a sister system. This can lead to data loss. When tables are deleted, blocks that are no longer accessible remain occupied. In the ADMIN operational state, these blocks are transferred to free space administration with a **CHECK DATA WITH UPDATE**.
- Download the table without reading the records of the defective blocks, delete the table and load the downloaded records. The table data can be read in primary key sequence. The primary key values of the records in the defective block are not specified in the selection. This method is only possible if no index page of the B\* tree has been affected. Data loss occurs.

## System Error

Diagnosis of severe errors  
(-10000 < Error number <= -9000)  
Sometimes the database crashes.

- 1. After a crash, the start procedure copies the diagnosis files to a directory. In the standard, the parameter DiagnoseHistoryPath is set to <RUNDIRECTORY>/DIAGHISTORY. Only two versions of these files are kept (parameter DiagnoseHistoryCount)
- 2. After the crash:
  - Try to restart the database (with vtrace switched on)
  - 3. Check, if the error can be reproduced (with vtrace switched on)
  - 4. Inform the support group, if the cause could not be identified – open a customer message.

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 109

Diagnosis files only have to be explicitly saved if they are not automatically copied to the DIAGHISTORY.

Settings for the collection of historical crash information can be done via the parameters DiagnoseHistoryPath (DIAG\_HISTORY\_PATH) and DiagnoseHistoryCount (DIAG\_HISTORY\_NUM).

### Message -602 in Syslog

Zeit	Typ	Nr.	Man.	Benutzer	Tcod	MNr	Text	Datum:
10:48:07	DIA	1	000	E30	SE38	BYL	Datenbankfehler -602 erfordert Intervention durch Datenbankadministrator	
10:48:07	DIA	1	000	E30	SE38	BY4	Datenbankfehler -602 beim SEL-Zugriff auf Tabelle ZZTELE_902 aufgetreten.	
10:48:20	DIA	1	000	E30	SE38	AB0	Laufzeitfehler "DBIF_RSOL_SOL_ERROR" aufgetreten.	
10:48:20	DIA	1	000	E30	SE38	AB1	> Kurzdump "050217 104820 p34777 E30" erstellt.	

How can database problems be analysed using db50?

- Example 1: -9026 Bad Data Page
- Example 2: -9028 Bad File

How does MaxDB support do an analysis if the database can no longer be transferred to the Online operational state (DB state Admin)?

- Analyze pages
- Restart record

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 110

MaxDB system errors are "mapped" to the general error -602 in the WebAS System. So this error number does not tell you much.

If the database is still in the ONLINE operational state or has restarted it following a crash, the analysis can be continued with transaction db50.

If restarting the database is no longer possible, other measures are required.

## DB50: Problem Analysis -9026 Bad Data Page

SAP

The screenshot shows the SAP ABAP runtime interface. The title bar reads "ABAP-Laufzeitfehler". The main area displays an error message: "ABAP-Laufzeitfehler DBIF\_DSQL2\_SQL\_ERROR aufgetreten am 10.12.2001 um 09:35:44". Below this, the database error text is shown: "Fehlertext der Datenbank...: "System error: BD Bad datapage"" and "Auslösende SQL-Anweisung...: "select count( \* ) from zztele\_9026"". It also includes internal information like "Interne Aufrufcodierung...: "[DBDS/NEW DSQL]" and instructions for troubleshooting. At the bottom, there's a note about sending logs to SAP and a list of steps for generating a dump. The status bar at the bottom right shows "SQ2 (2) (000) uw1019 INS".

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 111

A short dump with error -602 'BD Bad Data Page' occurred during execution of the ABAP report ZZ\_SEL\_9026.

The short dump thus provides more detailed information about the error than the system log and returns the corresponding text from the database.

## DB50: Error Texts and Codes

SAP

The screenshot shows the SAP DB50 interface. On the left, a tree view under 'E30' shows various database monitoring and analysis tools. A context menu is open over the 'Fehlertext bestimmen' (Determine error text) option, listing 'Fehlertext bestimmen', 'Fehler-Codes', and 'Freie Tabellenabfrage'. On the right, a table titled 'MESSAGES' is displayed with the following data:

MSGNO	LANGUAGE	MSGTEXT
9.044	ENG	System error: BD Inconsistent nodetype
9.043	ENG	System error: BD Fdir access not allowed
9.042	ENG	System error: BD Append not allowed
9.041	ENG	System error: BD Index not accessible
9.040	ENG	System error: BD Dropping of fdir not allowed
9.033	ENG	System error: Bad converter bitmap page
9.032	ENG	System error: BD Bad convertpage
9.030	ENG	System error: BD Bad logpage
9.029	ENG	System error: BD Bad infile
9.028	ENG	System error: BD Bad file
9.027	ENG	System error: BD Bad fdir
9.026	ENG	System error: BD Bad datapage
9.024	ENG	System error: BD Invalid entrypos
9.023	ENG	System error: BD Illegal entrypos
9.020	ENG	System error: BD Init missing
9.010	ENG	System error: BD Buffer limit

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 112

In the initial menu for transaction db50, you can find the text that corresponds to a particular number via **Utilities -> Determine error text**. The text for error -602, however, is not terribly helpful as it is too general.

**Utilities-> Error Codes** provides information about (system) error numbers as well as their texts by displaying the Messages table.

In the present example, **KnlMsg/knldiag** must be utilized for further analysis.

## DB50: Problem Analysis - Messages

SAP

The screenshot shows the SAP DB50: Problem Analysis - Messages interface. The title bar reads "DB50: Problem Analysis - Messages". The menu bar includes "Datenbankmeldungen", "Bearbeiten", "Springen", "System", and "Hilfe". The SAP logo is in the top right corner. The main window has a toolbar at the top with various icons. Below the toolbar is a menu bar with "Aktuelle Meldungen", "Alte Meldungen", and "Fehlermeldungen". The central area displays a table titled "Aktuelle Datenbankmeldungen (800 Kilobyte)". The table has columns: Zeit, PID, Typ, MsgID, Label, and Meldungstext. The data in the table is as follows:

Zeit	PID	Typ	MsgID	Label	Meldungstext
09:35:40	15	ERR	54001	I/O	page 00159A47010D0200...00000000020D0200
09:35:40	15	ERR	54001	I/O	BAD DATA PAGE 1415751
09:35:40	15	ERR	54001	I/O	on DEVNO 2 DEV_OFFSET 22177
09:35:40	15	ERR	53016	I/O	/sapdb/SQ2/sapdata/DISKD0002
09:35:42	15	ERR	54001	I/O	page 00159A47010D0200...00000000020D0200
09:35:42	15	ERR	54001	I/O	BAD DATA PAGE 1415751
09:35:42	15	ERR	54001	I/O	on DEVNO 2 DEV_OFFSET 22177
09:35:42	15	ERR	53016	I/O	/sapdb/SQ2/sapdata/DISKD0002
09:35:44	15	ERR	54001	I/O	page 00159A47010D0200...00000000020D0200
09:35:44	15	ERR	54001	I/O	BAD DATA PAGE 1415751
09:35:44	15	ERR	54001	I/O	on DEVNO 2 DEV_OFFSET 22177

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 113

To display the messages of the database system (*KnIMsg/knldiag*), choose **Problem Analysis->Messages**.

The error 'Bad Data Page' with error number -9026 is logged.

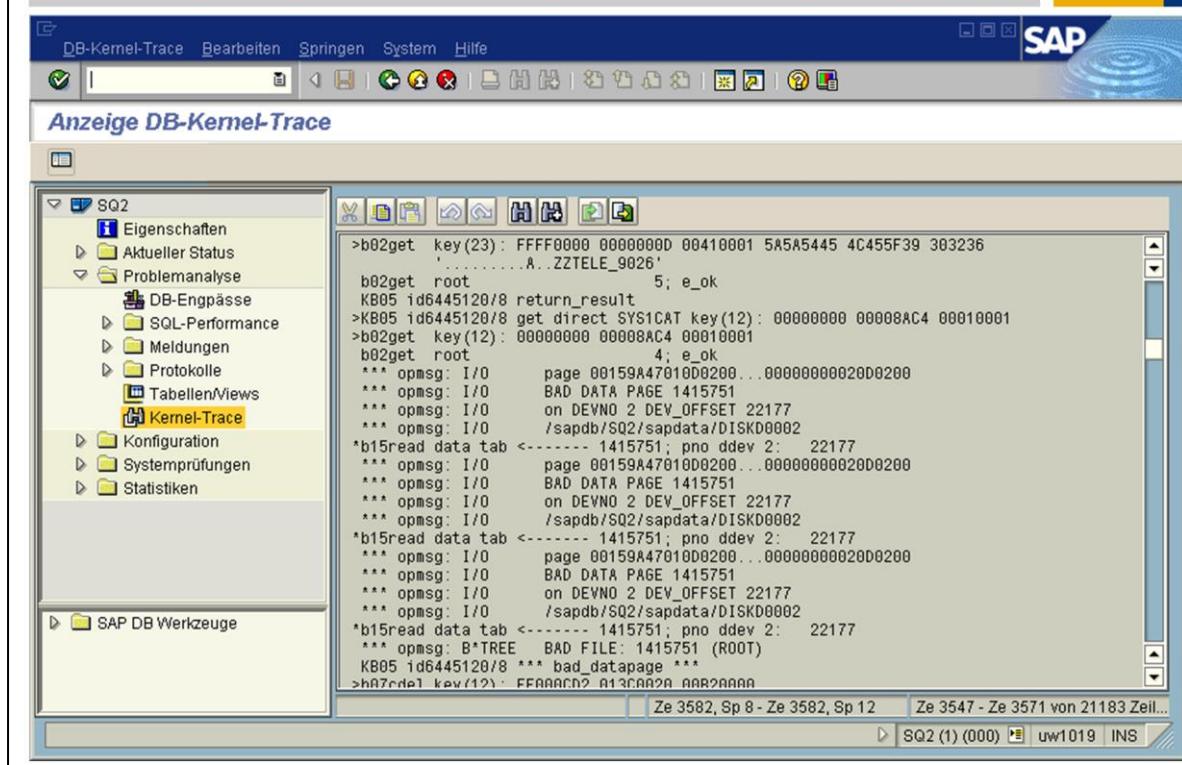

The root page of the affected object 1415751 is also recorded.

The position of the object is also logged. The defective object is located in Data Volume Number 2 at position 22177.

For a more precise analysis as to what is wrong with this object, the kernel trace (Vtrace) can be useful.

# DB50: Problem Analysis – Kernel Trace

SAP

Using db50, a Vtrace has been created.

The root page of the affected object 141575, the volume ( DevNo 2) and the position in the volume (22177) are logged.

In addition, an important section of the affected page is logged in the Vtrace which allows you to identify the cause of error -9026.

Each page has one so-called header and one trailer entry, consisting of 8 bytes each. Both entries are checked when the page is accessed.

Header entry: Page: 00 15 9A 47 01 0D 02 00

Trailer entry: Page: 00 00 00 00 02 0D 02 00

If inconsistencies appear when the header and trailer are compared, the 'Bad data page' error is sent to the application.

In this example we see that the first 5 bytes in the trailer differ from the header.

If the affected object is a database table, the database must be restored.

## Example -9026: Solution

- Check, if the affected object is a table.
- Examine volume 2, if there are hardware problems.
- Remove hardware problem.
- Restore of the database
- CHECK DATA with transaction db13

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 115

If the affected object is an index, error -9026 could be remedied by simply deleting and recreating the index; the cause of the problem, however, would not be solved.

The hardware must be examined in any event as such cases (-9026) can be due to hardware errors.

# DB50: Problem Analysis -9028 BD BAD FILE

SAP

The screenshot shows the SAP ABAP debugger interface. The title bar reads "ABAP-Laufzeitfehler". The main area displays an error message:

**ABAP-Laufzeitfehler** DBIF\_DSQL2\_SQL\_ERROR  
aufgetreten am 07.12.2001 um 11:55:12

Fehlertext der Datenbank...: "System error: BD Bad file"  
Auslösende SQL-Anweisung...: "insert INTO zztele\_bad values ( ?, ?, ?, ?, ?, ? , ? , ? , ? )"  
Interne Aufrufcodierung....: "[DBDS/NEW DSQL]"  
Bitte die Einträge im SAP-Systemlog auswerten (Transaktion SM21).  
Falls der Fehler in einem nicht modifizierten SAP-Programm vorkommt  
findet sich vielleicht eine Vorablösung im SAP-Hinweissystem.  
Falls Sie selbst Zugang zum SAP-Hinweissystem haben, so suchen Sie  
bitte zunächst mit folgenden Schlagworten:  
"DBIF\_DSQL2\_SQL\_ERROR"  
"ZZ\_INS\_9028" bzw. "ZZ\_INS\_9028"  
"START-OF-SELECTION"

Falls Sie das Problem nicht selbst lösen können, so senden Sie bitte  
folgende Unterlagen an SAP:

1. Ausdruck der vorliegenden Problembeschreibung  
Hierzu wählen Sie bitte in der aktuellen Anzeige die Funktion  
"Drucken" aus.

At the bottom right of the window, there is a toolbar with icons for SQ2 (1) (000), uw1019, and INS.

Report zz\_ins\_9028 terminated with a short dump.

The cause of the error, -602 'BD Bad File', can be seen in the short dump.

## DB50: Problem Analysis – Messages

SAP

The screenshot shows the SAP DB50: Problem Analysis – Messages interface. The main window title is "Ausgabe einer Meldungsdatei". On the left, there is a navigation tree with categories like Kernel-Threads, I/O-Operationen, Kritische Abschnitte, SQL-Sperren, Speicherbereiche, Systemeinstellungen, Transaktionen, Problemanalyse, DB-Engpässe, SQL-Performance, and Meldungen. Under Meldungen, there are sub-folders for Kern (Aktuell, Alt, Fehler) and Database Manager. The right side displays a table titled "Aktuelle Datenbankmeldungen (800 Kilobyte)" with columns: Datum, Zeit, PID, Typ, MsgID, Label, and Meldungstext. The table lists several messages, with two specific entries highlighted in red: "12-07 11:55:11 15 ERR 53000 BTREE Bad file for Root: 911813" and "12-07 11:55:11 15 ERR 51080 SYSERROR -9028 BD Bad file". The bottom status bar shows "SQ2 (1) (000) uw1019 INS".

Datum	Zeit	PID	Typ	MsgID	Label	Meldungstext
12-07	11:47:32	15		11007	COMMUNIC	wait for connection T44

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 117

The current example has the error "-9028 Bad File": access to the table has been blocked because a serious error (e.g. -9026) occurred.

The root page number is recorded in **KnIMsg/knldiag**. You can find out the table with the root page number.

## DB50: MaxDB Tools

SAP

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 118

Until version 7.7 you will find out which database object is affected by accessing the view ROOTS.

We have already seen how commands can be sent interactively to the database using the SQL Studio. The SQL Studio can be started directly from transaction db50.

The ROOTS table contains the root page number, the object type and the name of the database object for all database objects.

As of version 7.8 the following command can be used to determine the database object:

```
SELECT t.tablename, f.* FROM files f, tables t
WHERE (f.primaryfileid = t.tableid OR f.fileid = t.tableid)
AND f.root = 911813
```

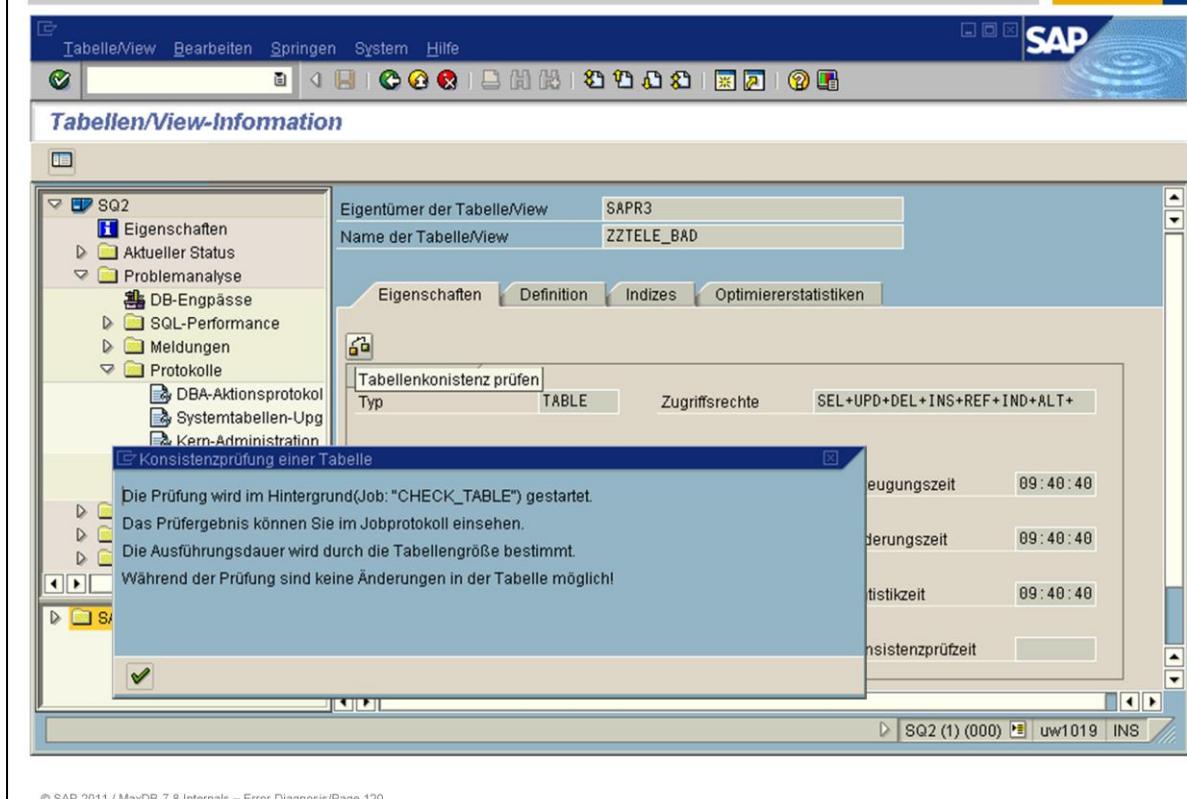

## Example – Field Types in the view roots

- SYS System table (not accessible)
- NAMED INDEX named index
- TABLE Table
- SHORT STRING FILE contains the short LOB COLUMNS  
(exists for each table with LOB COLUMNS)
- LONG COLUMN contains the long LOBs (OWNER, TABLENAME and  
INDEXNAME not specified)
- TEMP temporary table

## DB50: CHECK TABLE

SAP

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 120

In the present example, we know that table zztele\_bad has caused a problem; a consistency check is triggered.

A Check Table is executed on the table.

Check Table checks the tree structure of the B\* tree, header-trailer and so on.

If no inconsistencies are found, the BAD flag is retracted and access to the table is enabled.

This can happen if, for example, a Raid system reports an error but then corrects it immediately. Then the table is consistent, but has nevertheless been set to BAD.

## SM37: Job Log Check\_table

SAP

The screenshot shows the SAP SM37: Job Log Check\_table interface. The title bar reads "Job-Log zu Job CHECK\_TABLE". The main area displays a log entry for a job named "CHECK\_TABLE". The log details the execution of a check table step, starting at 13:05:00 on 07.12.2001, which successfully completed at 13:05:04. The log also shows the step was started by user SQ2. The bottom status bar indicates the job was run by user SQ2 (3) (000) and was inserted (INS).

Datum	Uhrzeit	Nachrichtentext	N-Klasse	N-Nummer	N
07.12.2001	13:05:00	Job wurde gestartet	00	516	
07.12.2001	13:05:01	Step 001 gestartet (Programm RSADACHT, Variante &0000000000001, Benutzername SQ2)	00	550	
07.12.2001	13:05:03	Tabellenprüfung für Tabelle "ZZTELE_BAD" erfolgreich beendet	SADA	115	
07.12.2001	13:05:04	Job wurde beendet	00	517	

The 'Check Table' executed without problems and reported no errors.

The program that had terminated with -9028 or -602 System Error can now be restarted.

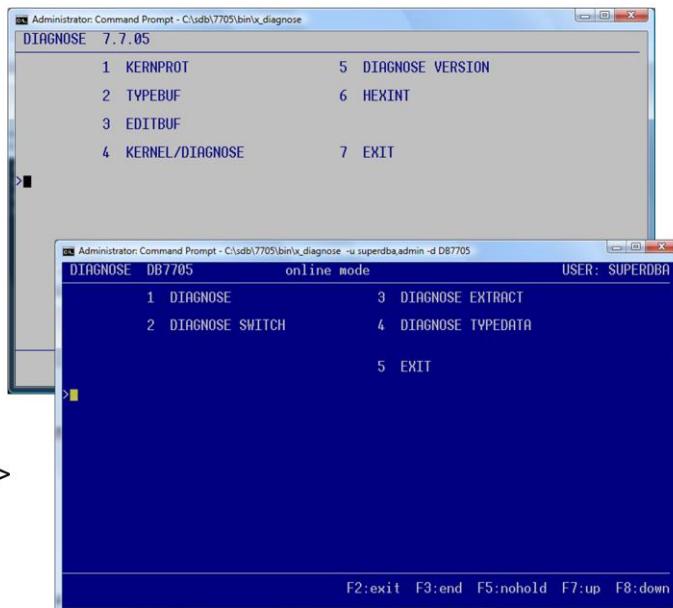

- Direct access to database pages (data, converter, log)

- Extraction of B\* trees

- Analysis of knldump

- Command:

```
<instroot>/bin/x_diagnose
```

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 122

The tool **x\_diagnose** allows you to access log pages and data pages in the database directly. With **x\_diagnose**, you can export configuration or restart information from the pages.

If necessary, you can extract an entire table tree.

x\_diagnose is also used to evaluate **knldumps**. Cache contents, converter information, lock list entries, etc., can be analyzed at a later time.

Because improper use of the tool can be dangerous, **x\_diagnose** should only be used by development.

In exceptional cases, pages can be repaired directly using an editing function.

Depending on the call of **x\_diagnose** (with or without user/password combination for the database administrator) different menus were offered.

## Diagnosis: Data Page (1)

The screenshot shows two terminal windows side-by-side. The left window is titled 'Command Prompt - telnet p34777' and displays the 'DIAGNOSE 7.5.0' menu with the following options:

1 KERNPROT	5 DIAGNOSE VERSION
2 TYPEBUF	6 HEXINT
3 EDITBUF	
4 KERNEL/DIAGNOSE	7 EXIT

The right window is also titled 'Command Prompt - telnet p34777' and shows the command 'TYPEBUF 7.5.0' entered. It prompts for a volume/input file path: 'VOLUME/INPUTFILE: /sapdb/E30/sapdata/DISKD0002'. It also asks for 'PAGES PER BLOCK : 1' and 'REWIND WHEN CLOSING? n'. At the bottom of the window, there is a status bar with keyboard shortcuts: F2:exit F3:end F5:nohold F7:up F8:down.

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 123

The following pages show how to extract a data page with **Diagnose**.

First you choose TYPEBUF.

Then you enter the volume name.

The following slides show the x\_diagnose tool of version 7.5; the menus are still identical in 7.7.

## Data Page (2)

```
ca Command Prompt - telnet p34777
TYPEBUF 7.5.0          SELECT FUNCTION      /sapdb/E30/sapdata/D
1 ALL                  10 MINBUF
2 FROM/TO              11 -
3 GET BLOCK            12 BUFLength
4 -                    13 LOWER/UPPER BOUND
5 SEARCH DUMP          14 SEARCH PAGE
6 SCAN                 15 SEARCH ON LOG VOLUME
7 NOSCAN               16 HEXINT
8 -                    17 -
9 NODISPLAY            18 NEXT INPUTFILE
>6
                                         F2:exit  F3:end  F5:nohold  F7:up   F8:down
```

## Data Page (3)

```
Command Prompt - telnet p34777
TYPEBUF 7.5.0
/sapdb/E30/sapdata/D

node:
  F = node header
  K = key      S = key (short info: first/last key of node)
            M = key (minbuf/maxbuf)
  R = record/object

log:
  H = logentry (header only)           dump:
  L = logentry                         D = dump label
  G = logentry (minbuf/maxbuf)         F = full info

BD pages (converter):
  B = BD full info

other pages (restartrec, log info, hostfile info, etc.):
  F = full info

SELECT CHAR: f_
```

F2:exit F3:end F5:nhold F7:up F8:down

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 125

Using the SCAN menu, you can then specify what information you desire.

## Data Page (4)

The screenshot shows two terminal windows side-by-side. Both windows have a title bar 'Command Prompt - telnet p34777' and a path bar '/sapdb/E30/sapdata/D'.  
The left window displays a menu of functions numbered 1 through 19:

TYPEBUF	7.5.0	SELECT FUNCTION	/sapdb/E30/sapdata/D
1	ALL	10	MINBUF
2	FROM/TO	11	-
3	GET BLOCK	12	BUFSIZE
4	-	13	LOWER/UPPER BOUND
5	SEARCH DUMP	14	SEARCH PAGE
6	SCAN	15	SEARCH ON LOG VOLUME
7	NOSCAN	16	HEXINT
8	-	17	-
9	NODISPLAY	18	NEXT INPUTFILE
		19	RETURN

The right window shows the result of entering function 3 (GET BLOCK) followed by the block number 21777:  
BLOCK NO 21777  
F2:exit F3:end F5:nhold F7:up F8:down

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 126

By specifying a block address - taken, for example, from ***KnIMsg (knldiag)*** - you come to the desired page.

## Data Page (5)

## Diagnosis: Restart Record (1)

The image shows two terminal windows side-by-side. Both windows have a title bar 'Command Prompt - telnet p34777' and a user identifier 'USER: CONTROL'.  
The top window displays a menu with the following options:

DIAGNOSE E30	online mode	USER: CONTROL
1 DIAGNOSE	3 DIAGNOSE EXTRACT	
2 DIAGNOSE SWITCH	4 DIAGNOSE TYPEDATA	
5 EXIT		

  
The bottom window displays a more detailed menu with the following options:

DIAGNOSE E30	SELECT FUNCTION	USER: CONTROL
1 GET DATA PERM	10 MINBUF	
2 GET DATA STATIC	11 -	
3 -	12 BUFSIZE	
4 GET LOG INFO	13 LOWER/UPPER BOUND	
5 GET RESTART RECORD	14 -	
6 SCAN	15 -	
7 NOSCAN	16 HEXINT	
8 -	17 -	
9 NODISPLAY	18 -	
	19 RETURN	

© SAP 2011 / MaxDB 7.8 Internals – Error Diagnosis/Page 128

You want to check the restart record.

You can access the restart record in various ways. One way is to choose KERNEL/DIAGNOSE, which brings you to the menus displayed here.

## Restart Record (2)
